

Untypical examples and insufficient or weighted evidence

Three questions:

- 1 Is my generalisation based on a sufficient number of observed instances?
- 2 Do these instances represent a fair sample?
 - 2.1 Are they typical?
 - 2.2 Are there any special conditions prevailing?
 - 2.3 Are there any exceptions?
- 3 What is the probability of such a generalisation being true? Does this make it reasonable to believe it *is* true?
