

Fundamental of Data Structures

Prof. Amit Dangi

Outline-Unit-1

- Data Management concepts
- Data types – primitive and non-primitive
- Types of Data Structure – linear and non-linear
- Abstract Data Types

Data Management Concepts

Data Management Concepts

❑ What is Data?

- ▶ **Data** is the basic fact or entity that is utilized in calculation or manipulation.
- ▶ There are two different **types of data** - **Numeric** data and **Alphanumeric** data.
- ▶ When a programmer collects such type of data for **processing**, he would require **to store them in computer's main memory**.
- ▶ The process of storing data items in computer's main memory is called ***representation***.
- ▶ **Data** to be processed must be **organized in a particular fashion**, these organization leads to structuring of data, and hence the mission to study the Data Structures.

Data Types

Data Types

❑ What is Data types?

- ▶ A **data type** is a classification of data, which can store a specific type of information.
- ▶ Data Type = Basic Data Type = Primitive Data Type

Data Types

❑ Primitive Data Types

- ▶ A **primitive data** type is predefined by the language and is named by a reserved keyword.
- ▶ Primitive data types are predefined, supported by C language.
 - int, char, float, double.

Data Types

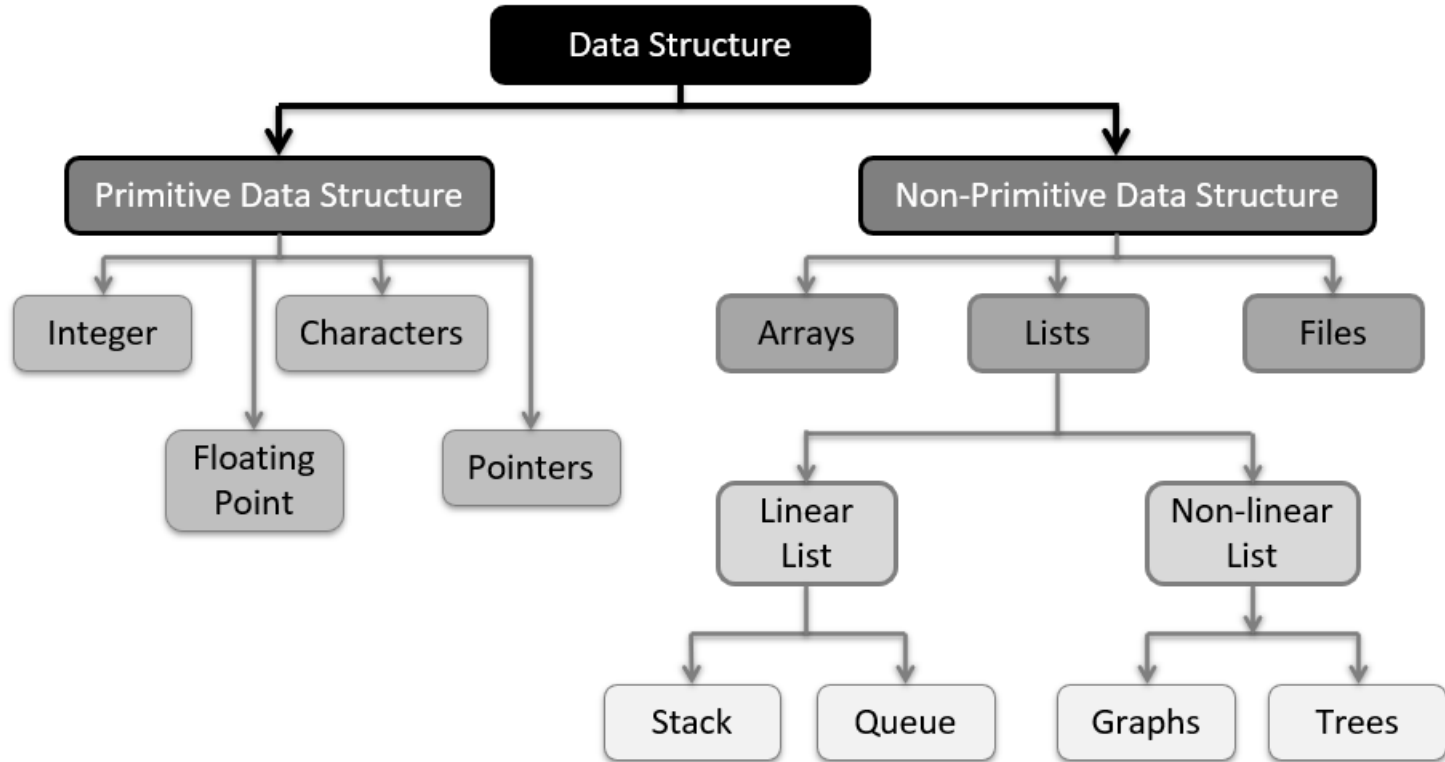

❑ Non-primitive Data Types

- ▶ **Non-Primitive** data types are not defined by C language, but are created by the programmer.
- ▶ They are created using the basic data types.
- ▶ Example:
 1. Linked List
 2. Stacks
 3. Queue
 4. Graph

Types of Data Structure

Types of Data Structure

Primitive Data Structure

► Primitive data structures

- Primitive data structures are basic structures and are directly operated upon by machine instructions.
- *Integers*, *floats*, *character* and *pointers* are examples of primitive data structures.

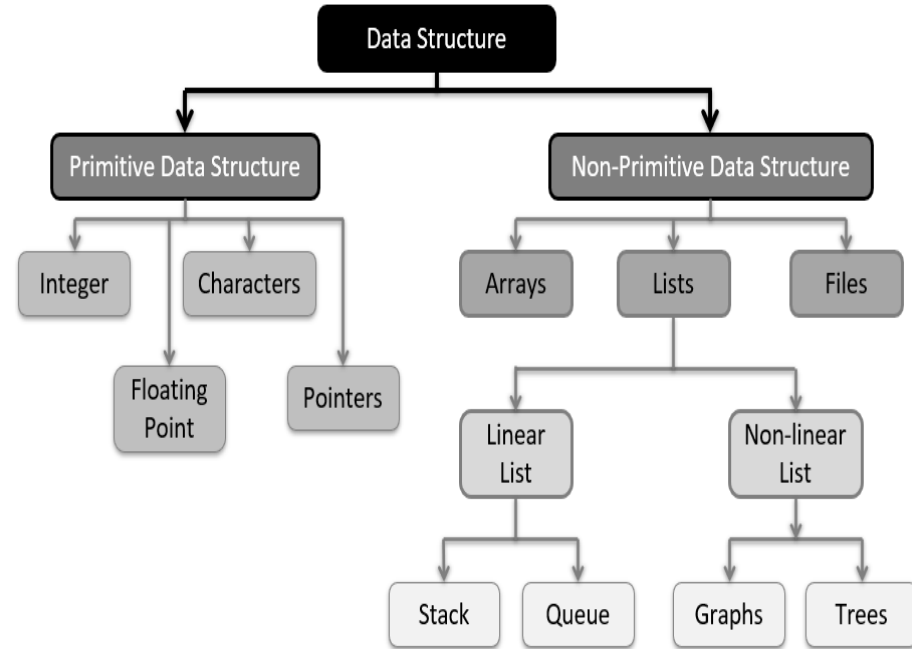

Non-Primitive Data Structure

► Non primitive data structure

- These are derived from primitive data structures.
- The non-primitive data structures emphasize on structuring of a group of homogeneous or heterogeneous data items.
- Examples of Non-primitive data type are *Array*, *List*, and *File*.

Non-Primitive Data Structure

- ▶ **Array:** An array is a fixed-size sequenced collection of elements of the same data type.
- ▶ **List:** An ordered set containing variable number of elements is called as Lists.
- ▶ **File:** A file is a collection of logically related information. It can be viewed as a large list of records consisting of various fields.

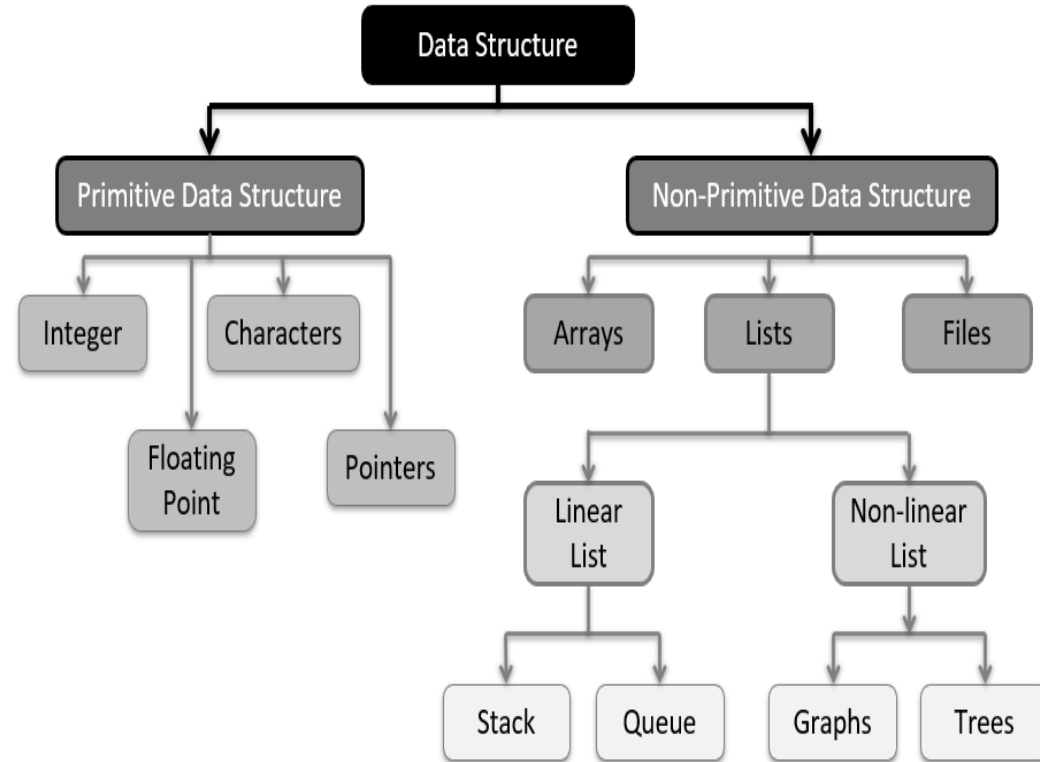

Linear Data Structure

► Linear data structures

➔ A data structure is said to be Linear, if its elements are connected in linear fashion by means of logically or in sequence memory locations.

➔ Examples of Linear Data Structure are **Stack** and **Queue**.

Non-linear Data Structure

► Nonlinear data structures

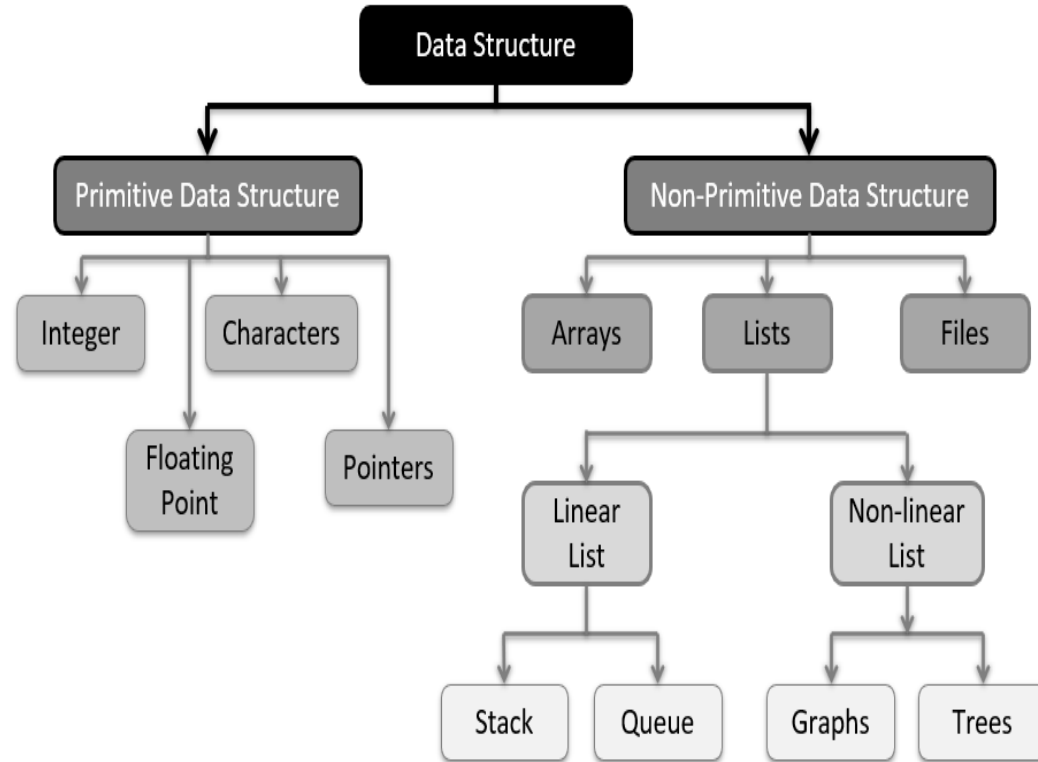

- ➔ Nonlinear data structures are those data structure in which data items are not arranged in a sequence.
- ➔ Examples of Non-linear Data Structure are **Tree** and **Graph**.

Graph

Abstract Data Types

The image features a light gray background with a stack of white papers on the right side. A white, curved object, possibly a pen or a piece of paper, is resting on top of the papers. The text "Abstract Data Types" is written in a bold, dark gray font on the left side of the image.

Abstract Data Types

- ▶ ***Abstract Data type (ADT)*** is a type (or class) for objects whose behavior is defined by a set of values and a set of operations.
- ▶ The definition of ADT only mentions what operations are to be performed but not how these operations will be implemented.
- ▶ It does not specify how data will be organized in memory and what algorithms will be used for implementing the operations. It is called “**abstract**” because it gives an implementation-independent view.

Abstract Data Types

► Example:

- ❑ Whenever end user uses Stack, he is concerned about only the type of data and operations that can be performed on it.
- ❑ Fundamentals of how the data is stored is invisible to users.
- ❑ They will have `push()` and `pop()` functions only.

Data Structure

The background of the slide is a photograph of a stack of white papers. On the right side, a white, curved object, possibly a piece of paper or a small container, is partially visible. The text 'Data Structure' is printed in a bold, dark grey font on the left side of the image.

Introduction to Data Structure

❑ What is Data Structure?

- ▶ A data structure is a **way of organizing all data items** that **considers** not only the **elements stored** but also their **relationship to each other**.
- ▶ We can also define data structure as a **mathematical or logical model** of a particular **organization** of **data items**.

Operation of Data Structure

- ▶ **Create:** It results in reserving memory for program elements.
- ▶ **Destroy:** It destroys memory space allocated for specified data structure.
- ▶ **Selection:** It deals with accessing a particular data within a data structure.
- ▶ **Updation:** It updates or modifies the data in the data structure.
- ▶ **Searching:** It finds the presence of desired data item in the list of data items.
- ▶ **Sorting:** It is a process of arranging all data items in a data structure in a particular order.
- ▶ **Merging:** It is a process of combining the data items of two different sorted list into a single sorted list.
- ▶ **Splitting:** It is a process of partitioning single list to multiple list.
- ▶ **Traversal:** It is a process of visiting each and every node of a list in systematic manner.

A hand holding a white, shield-shaped sign with the words "Thank You" written in blue. The background is a solid blue color.

Thank
You
