Managing Adult Medical Emergencies in the Dental Office

Course Author(s): Palma A. Freydinger, DDS; Fady F. Faddoul, DDS, MSD
CE Credits: 4 hours
Intended Audience: Dentists, Dental Hygienists, Dental Assistants, Office Managers, Dental Students, Dental Hygiene Students, Dental Assistant Students
Date Course Online: 09/16/2016  Last Revision Date: N/A  Course Expiration Date: 09/15/2019
Online Course: www.dentalcare.com/en-us/professional-education/ce-courses/ce516

Introduction
Participants in this course will be introduced to information essential to diagnose and respond to adult medical emergencies in oral healthcare settings. Special emphasis is placed on factors to be considered in risk-assessment, recognizing medical emergencies that are immediately life-threatening and must be acted upon promptly (e.g., cardiac arrest); and those problems that, while not immediately life-threatening, require timely stabilization (e.g., hypoglycemia).

ADA CERP
The Procter & Gamble Company is an ADA CERP Recognized Provider.

ADA CERP is a service of the American Dental Association to assist dental professionals in identifying quality providers of continuing dental education. ADA CERP does not approve or endorse individual courses or instructors, nor does it imply acceptance of credit hours by boards of dentistry.

Concerns or complaints about a CE provider may be directed to the provider or to ADA CERP at: http://www.ada.org/cep

Approved PACE Program Provider
The Procter & Gamble Company is designated as an Approved PACE Program Provider by the Academy of General Dentistry. The formal continuing education programs of this program provider are accepted by AGD for Fellowship, Mastership, and Membership Maintenance Credit. Approval does not imply acceptance by a state or provincial board of dentistry or AGD endorsement. The current term of approval extends from 8/1/2013 to 7/31/2017.

Overview
Participants in this course will be introduced to information essential to diagnose and respond to adult medical emergencies in oral healthcare settings. Special emphasis is placed on factors to be considered in risk-assessment, recognizing medical emergencies that are immediately life-threatening and must be acted upon promptly (e.g., cardiac arrest); and those problems that, while not immediately life-threatening, require timely stabilization (e.g., hypoglycemia).

Learning Objectives
Upon completion of this course, the dental professional should be able to:
• Discuss factors to consider in the risk stratification of patients with systemic diseases.
• Discuss essential elements of being prepared for a medical emergency in the oral healthcare setting.
• Recognize signs and symptoms and formulate a diagnosis for an emerging perioperative problem.
• Initiate timely action to stabilize the patient before emergency medical services arrive.

Introduction
The primary obligation and ultimate responsibility of oral healthcare personnel (OHCP) is the timely delivery of quality preventive, diagnostic, and therapeutic services within the bounds of the clinical circumstances presented by patients. Because an ever-increasing number of patients with medical problems seek dental treatment, OHCP can expect to face situations that may threaten the physical well-being of at-risk patients.

It follows that OHCP must possess the knowledge and skills essential to determine their patients’ physical and emotional ability to undergo and respond to dental care. Diagnostic activities should be effective to establish a database that will serve as reference points for significant medical problems and, importantly, the database must identify those patients at-risk who may experience a medical emergency during the perioperative period.

The best available data on the types and incidence of medical emergencies in oral healthcare settings is based on two independent prospective surveys. Over a 10-year period, 4,309 dentists documented 30,602 medical emergencies (Box A) that fell into six major categories: (1) cardiovascular, (2) respiratory, (3) endocrine, (4) allergic, (5) neurogenic, and (6) toxic events. The data also indicate that the rate of medical emergencies per dentist per year is low (0.5/year).

Being ill prepared to respond to emerging perioperative medical events is inexcusable; being subjected to public censure or accused of negligence is an agony best prevented. Consequently, OHCP must P-R-A-Y, i.e., (1) “P”repare for the role of “first responders;” (2) “R”ecognize predisposing factors and signs and symptoms of medical emergencies; (3) “A”ct to stabilize the patient; and (4) “Y”ell for help, i.e., activate emergency medical services (EMS).

OHCP must provide emergency care appropriate for the emergent setting (i.e., oral healthcare facility). At the very minimum,
in the event of a life-threatening medical emergency, OHCP must feel comfortable to perform basic life support (BLS) techniques to stabilize the patient until EMS arrives. It must be emphatically stated that advanced life support (ALS) activities should not be attempted without sufficient training and maintenance of skills.

**Procedure-specific Risk Factors**

Every procedure elicits a stress-response, i.e., “surgical stress,” characterized by physiological (i.e., autocrine, endocrine, and paracrine) changes accompanied by psychological reactions (e.g., fear, anxiety, anger, tension, malaise or fatigue). The magnitude of these procedure-related responses is proportional to the severity of tissue trauma, duration of the procedure, volume of blood loss, fluid shifts, and changes in core body temperature.

Based on the above criteria, procedure-related stress can be classified as high, intermediate, and low with estimated rates of associated major medical events of >5%, 1-5%, and <1%, respectively (Box B). With low-stress procedures (e.g., dental procedures), the risk is negligible unless strong patient-specific risk factors are present. OHCP must identify patient-specific risk factors that may lead to medical emergencies during the perioperative period.

**Patient-specific Risk Factors**

“Never treat a stranger.” Identification of patient-specific risk factors is predicated on data obtained from the physical evaluation. Past and present illnesses; major hospitalizations; review of organ systems; family history; social history; history of drug allergies and other adverse drug effects; medications, vitamins and other dietary supplements (including special diets) currently taken by the patient must be considered in determining perioperative risk.

Since the stress-response is mediated primarily by the sympathoadrenal system, the history should also seek to determine the patient’s functional capacity (FC). FC relates to a person’s functional reserve, which correlates well with maximum oxygen uptake during treadmill testing and is expressed in metabolic equivalents (METs). One MET equals the resting or basal oxygen requirement (i.e., 3.5 ml of O₂ per kg per minute) of a 40-year-old, 70-kg man.

A validated method to determine FC, predicated on a person’s ability to perform a spectrum of common daily activities, is presented in Box C.

  - Gynecological procedures
  - Minor orthopaedic procedures
  - Minor urological surgery
FC is classified as excellent (>10 METs), good (7 METs to 10 METs), moderate (6 METs to 4 METs), or poor (<4 METs). The inability of a person to climb two flights of stairs or to run a short distance indicates poor functional capacity (<4 METs). When functional capacity is low, the risk of a medical emergency is high. For example, a person with no evidence of coronary artery disease (CAD), but who reports a history of sedentary lifestyle and has poor FC may benefit from a preoperative evaluation. Conversely, a patient considered high risk because of a history of CAD who is asymptomatic and runs 30 minutes daily may need no further cardiovascular testing before proceeding with planned dental procedures, i.e., when functional capacity is high, the risk of a medical emergency is low.

Physical examination is also part of risk assessment. A patient's mental state and general appearance, e.g., cyanosis, pallor, diaphoresis, shortness of breath, tightness and/or pain in the chest with minimal activity, tremor, anxiety, and peripheral edema are signs and symptoms that provide invaluable clues regarding the patient's overall health status. Critically, the physical examination must also include a determination of the patient's baseline vital signs Box D.

</thead>
</table>
| <4 METs | • Take care of yourself?  
• Eat, get dressed, or use the toilet?  
• Walk indoor around the house?  
• Walk 100 m on level ground at 3 to 5 km per hour |
| >10 METs | • Climb two flights of stairs or walk uphill, or run a short distance?  
• Do heavy work around the house like scrubbing floors or lifting or moving heavy furniture?  
• Participate in strenuous sports like swimming, singles tennis, football, basketball, or skiing? |

Box D. Vital Signs.

| Blood pressure | Normal: <120/80 mm Hg  
Prehypertension: 120-139/80-89 mm Hg  
Abnormal: <90/50 or ≥140-90 mm Hg |
|----------------|-----------------------------------|
| Pulse rate and rhythm | Normal – adult: 60-100 beats/min.  
Normal – child: 90-120 beats/min.  
Normal – aged: 70-89 beats/min.  
Abnormal: <90/50 or ≥140-90 mm Hg |
| Rate of respiration | Normal – adult: 16-20 breaths/min.  
Normal – child: 24-28 breaths/min.  
Abnormal: rates <10 or >20 breaths/min. |
| Body temperature | Normal: =37°C (orally)  
Maximum circadian variation: ±0.6°C  
Fever: ≥37.8°C (orally) |
Predicated on patient-specific risk factors identified during the physical evaluation, the American Society of Anesthesiology (ASA) Physical Status (PS) Classification system provides a practical method to quantify perioperative risk for patients undergoing surgical (and by extension dental) procedures (Box E). The rate of perioperative complications in medicine correlates closely to the ASA PS classification and ranges from 0.4/1000 for ASA PS I to 9.6/1000 for ASA PS IV.19

Box E. Modified ASA Physical Status Classification.16,17

| **ASA PS II**   | Minimal risk                |
| Patient with well-controlled mild systemic disease affecting one organ system | Well-controlled hypertension (HTN); diabetes mellitus (DM); respiratory problems, i.e., asthma or chronic obstructive pulmonary disease (COPD); seizure disorder |
| No substantive functional limitations | Mild obesity (BMI 30-39) |
| Good functional capacity | Pregnancy |
| 7 to 10 METs      |                             |

| **ASA PS III**  | No immediate risk           |
| Patient with one or more moderate-to-severe systemic disease | Poorly controlled DM or HTN |
| Substantive functional limitation (but not incapacitating) | Asymptomatic congestive heart failure (CHF) |
| Moderate functional capacity | Stable angina |
| 4 to 6 METs       | History of (>3 months) myocardial infarction, cerebrovascular accident (CVA), transient ischemic attack (TIA), or coronary artery stents |
|                   | Morbid obesity (BMI ≥40) |
|                   | End stage renal disease (ESRD), patient undergoing regularly scheduled dialysis |
|                   | Respiratory problems with intermittent symptoms (asthma, COPD) |

| **ASA PS IV**   | Possible risk               |
| Patient has at least one severe systemic disease that is poorly controlled or at end-stage that is a constant threat to life | History of recent (<3 months) of MI, CVA, TIA |
| Substantive functional limitation (incapacitating) | Unstable angina |
| Poor functional capacity | Severe valve dysfunction |
| <4 METs            | Symptomatic COPD |
|                    | Symptomatic CHF |
|                    | Hepato-renal failure |
|                    | ESRD, patient not undergoing regularly scheduled dialysis |

| **ASA PS V**    | Imminent risk               |
| Moribund patients, not expected to survive 24 hours without medical or surgical intervention | Multi-organ failure |
| No residual functional reserve |                             |
“First, Do No Harm” (Hippocratic Oath)
Develop a medical emergency team (Box F). Know what to look for – be familiar with predisposing factors and signs and symptoms of medical emergencies. Be alert – monitor the patient’s physical and emotional status during treatment – look for evidence of distress or adverse reactions, particularly when drugs are being administered to the patient. Train under simulated conditions. Check regularly the status of emergency drugs and other equipment (Box F).

Primary Survey
When faced with an emerging perioperative medical event, the following hierarchical steps must be implemented in every situation: (1) assess responsiveness, (2) check airway, (3) and, simultaneously, check breathing and pulse (Box G). These fundamental activities comprise the primary survey (Box F), which identifies those problems that are immediately life-threatening and must be promptly acted upon, i.e., obstructed airway, respiratory arrest, or cardiac arrest.

The unresponsive patient in an oral healthcare setting depend on the office emergency team for (1) early recognition of airway obstruction, respiratory and/or cardiac arrest and activation of EMS, (2) early high-quality CPR to delay brain damage from lack of oxygen, (3) early defibrillation to restore an effective heart rhythm, and (4) early advanced life support and post-arrest care. For each minute CPR and/or defibrillation is delayed, the patient’s chances of survival is reduced by 7 to 10 percent.

Box F. Being Prepared.
Box G. Primary Survey: Every Patient.

Assess level of consciousness:
- Tap the patient on the shoulder and shout - “Are you OK?” (Figure 1)
  - Responsive patient
    - Alert
      - Awake and able to speak
    - Disoriented
      - May moan, cry, or make other sounds
      - Responds to verbal and/or painful stimuli, i.e., moves
  - Place responsive patient in the dental chair in an upright/semi-reclining position (Figure 2)
  - Unresponsive patient
    - Silent, does not respond to verbal and painful stimuli
    - Place unresponsive patient in the dental chair in a supine position on a firm, flat board (e.g., EMS board) to allow for adequate compressions later (Figure 3)
      - SUMMON THE OFFICE EMERGENCY TEAM
      - ACTIVATE EMERGENCY MEDICAL SERVICES (EMS)
Box G. Primary Survey: Every Patient. (continued)

Check airway:
- If the patient is responsive (i.e., alert and talking, even in a whisper) the airway is open, at least partially, at this time
- If the patient is unresponsive (i.e., does not respond to verbal and painful stimuli) evaluate airway
  - If the airway is not open, it may be due to relaxation of the soft tissues of the oropharynx
    - Perform head-tilt/chin-lift (Figure 4)
  - If obstruction is caused by foreign material it must be cleared
    - Suction thick, frothy, bloody saliva and vomitus
    - Foreign object must be removed (see Airway obstruction (foreign body))

Figure 4.

Look for breathing and check pulse (minimum 5 seconds; maximum 10 seconds):
- Simultaneously, see if the patient's chest rises and falls, listen for escaping air, and feel the airflow against the side of your cheek (Figure 5); and palpate the carotid artery (Figure 6)
  - Unresponsive patient
    - Normal breathing (quite, regular and effortless) and has a definite pulse
      - Monitor vital signs until EMS arrives
    - No normal breathing, but has a definite pulse
    - Initiate rescue breathing
      - 1 breath every 5-6 seconds (10 to 12 breaths/min.)
      - Check pulse every 2 minutes
        - If no pulse, begin cardiopulmonary resuscitation (CPR) and prepare for automated external defibrillation (AED) in accordance with current American Heart Association and/or American Red Cross guidelines.20,21
Box G. Primary Survey: Every Patient. (continued)

- No breathing or only agonal breaths (i.e., isolated or infrequent gasping) and no pulse - the patient is in cardiac arrest
- Begin CPR - cycles of 30 compressions and 2 breaths
  - Continue CPR until AED is turned on, the AED pads are applied, and the AED is ready to analyze the heart rhythm*
  - Ensure that everyone, including the rescuer performing CPR, is clear of the patient during AED rhythm analysis and shock
    - If the AED advises that a shock is not indicated
      - Resume CPR immediately until prompted by AED to allow rhythm check (about 2 minutes)
    - If the AED advises that a shock is indicated press the shock button
      - Resume CPR immediately until prompted by AED to allow rhythm check (about 2 minutes)
- Continue with CPR and defibrillation until EMS takes over or the patient starts to move

*If alone, the AED should be used as soon as it is determined that the patient is in cardiac arrest.
**Airway Obstruction (Foreign Object)**

Airway obstruction can lead to respiratory and cardiac arrest if not addressed quickly and effectively. A conscious patient clutching his/her throat is showing the universal sign of choking. Encourage patient to assume a comfortable position and cough forcefully until he/she can breathe normally. If the coughs become weak and ineffective activate EMS; place the patient in a supine position; and deliver quick, upward abdominal thrusts until the object is forced out (Figure 7).

If the patient becomes unresponsive, immediately begin CPR with chest compressions and make sure an AED is readily available. Each time the airway is opened to give ventilations, look for any visible objects in the oropharynx. If an object can be seen, remove it (if possible) using a finger sweep motion (Figure 8). If a foreign object is not visible, a blind finger sweep should not be performed; continue CPR, cycles of 30 compressions and 2 ventilations, until EMS arrives.

**Secondary Survey**

If the patient is conscious proceed with the secondary survey (Box H). Since the pulse rate and character and the rate and character of respiration have already been determined, assess the blood pressure at this time. Next, correlate the patient’s chief complaint and signs and symptoms to a specific organ system. The goal is to identify those problems that are not immediately life-threatening, but require timely stabilization (e.g., hypoglycemia, angina pectoris, ventilation failure).

Physical signs and symptoms are produced by physical causes and must be recognized before a physical problem can be diagnosed and treated. Without at least a presumptive or working diagnosis there is nothing to treat. Based on symptoms analysis, medical emergencies can be characterized as altered consciousness; chest pain; and ventilatory, allergic (pruritus, urticaria, angioedema), neurogenic (i.e., sensory, affective, motor), and toxic events (Box I).

**Syncope**

Syncope (Table 1) is defined as sudden brief loss of consciousness due to cerebral ischemia.
<table>
<thead>

| Altered sensory, affective and/or motor function | • Seizure  
• Cerebrovascular accident | • Syncope  
• Hyperventilation  
• Hypoglycemia |

*Airway obstruction, respiratory arrest, and cardiac arrest are discussed under primary survey.

**Rare office emergencies (e.g., thyrotoxicosis, Addisonian crisis and emergencies that evolve over hours or days (e.g., advanced diabetic ketoacidosis, extreme hyperosmolarity) are mentioned, but no separate protocols are presented.
In a young adult it is usually precipitated by a generalized, progressive autonomic discharge secondary to anxiety, pain, heat, or humidity. The initial adrenergic response to a stressor is followed by an overwhelming cholinergic surge just prior to unconsciousness. Syncope in patients over 50 years of age may likely be secondary to cardiovascular disorders (e.g., dysrhythmia, postural hypotension), hypoglycemia or cerebrovascular insufficiency.

Table 1. Syncope.

</tbody>
</table>

Figure 9.

Nota bene:
- Signs of recovery: vital signs return to baseline values, patient is alert
- Signs of deterioration: vital signs unstable, mental status labile
**Postural (Orthostatic) Hypotension**
Postural hypotension (Table 2) is defined as a decline of ≥20 mm Hg in the systolic BP, and/or a decline of ≥10 mm Hg in the diastolic BP, or an increase of ≥20 beats/minute in pulse rate, and abrupt symptoms of cerebral ischemia (syncope) following postural change from a supine to an upright position. It may be secondary to impaired homeostatic mechanisms of blood pressure regulation; age and/or cardiovascular-disease-related physiological changes; anti-hypertensive medications; and/or recent intake of food.

Table 2. Postural Hypotension.

**Prevention:**
- Identify at-risk patient
  - Schedule dental appointments 30 to 60 minutes after the ingestion of meals and medications
  - Ensure profound local anesthesia
    - Use local anesthetic agents containing a vasoconstrictor congruent with the patient’s functional capacity
  - Upon completion of procedures, allow at-risk patients to assume an upright position gradually over 2 minutes

**Signs and symptoms:**
- No prodromal signs and symptoms
- Abrupt syncope when patient assumes an upright position
  - A decline (from baseline) of 20 mm Hg or more in the systolic blood pressure AND/OR
  - A decline (from baseline) of 10 mm Hg or more in the diastolic blood pressure AND/OR
  - An increase (from baseline) in pulse rate of 20 beats per minute or more

**Emergency response:**
- Immediately return patient to supine position for 5-10 minutes
  - Administer oxygen
    - 4 to 6 L/min by nasal cannula
  - Reevaluate vital signs
- Allow patient to assume a sitting position for at least 2 minutes
  - Reevaluate vital signs
- Allow patient to stand for 2 minutes
  - Reevaluate vital signs
- If patient’s condition is deteriorating
  - Activate EMS
    - Monitor vital signs
    - If at any time the patient becomes unresponsive, no normal breathing, and no palpable pulse consider the diagnosis of cardiac arrest
      - Immediate CPR and defibrillation congruent with current recommendations

**Nota bene:**
- Signs of recovery: vital signs return to baseline values, patient is alert
- Signs of deterioration: vital signs unstable, mental status labile
- Postural hypotension, often observed in older patients, may result in significant morbidity from associated falls
  - The lack of prodromal signs and symptoms should prompt oral healthcare providers to take preemptive action.
Hypoglycemia
Plasma glucose concentration is closely regulated by the autonomic nervous system. Glucagon promotes hepatic glycogenolysis and gluconeogenesis and is a hyperglycemic agent. Insulin promotes cellular glucose uptake and is a hypoglycemic agent. Hypoglycemia (Table 3) is defined as sustained plasma glucose level <70 mg/dL. Heavy exercise, anxiety, and infection may cause hypoglycemia, but the most common cause is treatment with insulin and/or oral hypoglycemic agents and inadequate carbohydrate intake (delayed, decreased, or missed meals).

**Table 3. Hypoglycemia.**

**Prevention:**
- Identify at-risk patient
  - Confirm compliance with regimen of antidiabetic medications and food intake
  - Reduce anxiety
  - Ensure profound local anesthesia
    - Use local anesthetic agents containing a vasoconstrictor congruent with the patient’s functional capacity

**Signs and symptoms:**
- Signs and symptoms start to develop at plasma glucose values <65 mg/dL
  - Adrenergic manifestations
    - Twitching, tremor
    - Anxiety, nervousness
    - Sweating, cold, clammy skin
    - Pallor
    - Mydriasis
  - Glucagon manifestations
    - Hunger
    - Nausea, vomiting, abdominal discomfort
  - Neuroglycopenic manifestations
    - Fatigue, weakness, lethargy
    - Paresthesia
    - Flashes of light in the field of vision
    - Headache
    - Subtle reduction in mental capacity (plasma glucose level <65 mg/dL)
    - Impairment of action and judgment (plasma glucose level <40 mg/dL)
    - Focal or generalized seizure (plasma glucose level <30 mg/dL)
    - Hypoglycemic coma (plasma glucose level <10 mg/dL)

**Emergency response:**
- Place patient in a semi-reclining position (supine if patient becomes unconscious)
  - Mild hypoglycemia
    - If the patient is conscious, able to follow commands, and can swallow safely administer oral glucose in the form of glucose tablets (if available) otherwise a glass of fruit juice or 3 tbsp of sugar with water are acceptable alternatives
  - Severe hypoglycemia, i.e., loss of consciousness and/or seizure
    - Activate EMS
      - Apply a ribbon of sucrose paste (cake icing) on oral soft tissues or administer glucagon, 1 mg, IM or SL
      - Administer oxygen
        - 4 to 6 L/min by nasal cannula
      - Monitor vital signs
        - If at any time the patient becomes unresponsive, no normal breathing, and no palpable pulse consider the diagnosis of cardiac arrest
        - Immediate CPR and defibrillation congruent with current recommendations

**Nota bene:**
- Signs of recovering: improved mental state
- Signs of deterioration: vital signs unstable, mental status labile
Angina Pectoris
Angina pectoris (Table 4) is an acute coronary syndrome associated with transient ischemia to the myocardium. Hypoxia (and at times anoxia) results from diseases and conditions which lead to atherosclerosis and obstruction of coronary arteries by fatty deposits that limits and/or impairs coronary blood flow. Precipitating factors that increase cardiac oxygen demand in the presence of decreased perfusion of the myocardium include physical exertion, emotional stress, cold, recent meal. Unstable angina pectoris may occur spontaneously at rest.

Table 4. Angina Pectoris.

Prevention:
- Identify at-risk patient
  - Reduce anxiety
  - Ensure profound local anesthesia
    - Use local anesthetic agents containing a vasoconstrictor congruent with the patient’s functional capacity

Signs and symptoms:
- Mild to moderate substernal pain of sudden onset
  - Squeezing
  - Tight
  - Heavy
  - Radiates to the left shoulder, arm, and jaw
- BP ↑ from baseline

Emergency response:
- Place patient in an upright or semi-reclining position
  - Note the time and administer nitroglycerin
    - 0.4 mg, tablet/spray, SL
    - Administer oxygen
      - 2 to 4 L/min by nasal cannula
    - Reevaluate vital signs
  - If pain is not relieved 5 minutes after the initial dose, repeat nitroglycerin
    - 0.4 mg, tablet/spray, SL
    - Reevaluate vital signs
  - If pain is not relieved 10 minutes after the initial dose, repeat nitroglycerin
    - 0.4 mg, tablet/spray, SL
    - Reevaluate and record vital signs
- In a conscious patient, chest pain lasting more than 10 minutes must be assumed to be due to unstable angina or myocardial infarction
  - Activate EMS
  - Monitor vital signs
    - If at any time the patient becomes unresponsive, no normal breathing, and no palpable pulse consider the diagnosis of cardiac arrest
      - Immediate CPR and defibrillation congruent with current recommendations

Note bene:
- Signs of recovery: pain subsides, vital signs return to baseline values
- Signs of deterioration: persistent pain, unstable vital signs, altered mentation
- Adverse reaction to nitroglycerin includes flushing, headaches, dizziness, nausea, and vomiting; syncope and paradoxical angina pectoris due to nitrate-induced vasodilation has been reported
**Myocardial Infarction**

Myocardial infarction (Table 5) is caused by abrupt anoxia to a portion of the heart resulting in myocardial tissue necrosis. Anoxia results from conditions that lead to the formation of atherosclerotic plaques. In later stages, atherosclerotic plaques may become disrupted and contribute to thrombus formation. Atherosclerotic plaques and thrombi impair blood flow to large and medium-sized arteries of the heart. History of cardiovascular diseases, diabetes mellitus, and cerebrovascular disease increases the overall risk of perioperative MI.

### Table 5. Myocardial Infarction.

</tbody>
</table>
Hypertensive Emergency

Hypertension is defined as a blood pressure (BP) ≥140/90 mm Hg. Hypertensive emergency (Table 6) is defined by a BP ≥180/110 mm Hg and signs and symptoms of severely elevated BP. The mechanisms that lead to severely elevated BP appear to be related to a failure of normal autoregulatory function resulting in increased vascular resistance caused by endogenous vasopressors in patients with unrecognized or under-treated hypertension; and/or following the administration of sympathomimetic drugs such as high doses of epinephrine.

Table 6. Hypertensive Emergency.

Prevention:
- Identify at-risk patient
  - Reduce anxiety
  - Ensure profound local anesthesia
    - Use local anesthetic agents containing a vasoconstrictor congruent with the patient’s functional capacity

Signs and symptoms:
- Restlessness
- Flushed face
- Visual disturbances
- Dyspnea
  - Pulmonary edema/congestive heart failure
- A “hammering” pulse
- Altered mental state
- Chest pain
  - Myocardial ischemia, infarction, or aortic dissection
- Seizure
- Hypertensive encephalopathy
- Cerebral hemorrhage, coma, death

Emergency response:
- Place patient in an upright or semi-reclining position
  - Activate EMS
    - Administer oxygen
      - 4 to 6 L/min by nasal cannula
    - Monitor vital signs
      - If at any time the patient becomes unresponsive, no normal breathing, and no palpable pulse consider the diagnosis of cardiac arrest
        - Immediate CPR and defibrillation congruent with current recommendations

Nota bene:
- In the oral healthcare setting, the BP should not be acutely lowered.
  - Tissue perfusion in the brain, heart, and kidneys is tightly regulated within a certain range of mean arterial pressure (MAP), abruptly decreasing the MAP can lead to significant drop in cerebral blood flow and, thus, cerebral ischemia.
- Hypertensive urgency (BP ≥180/110 mm Hg, patient is asymptomatic)
  - Medical evaluation and risk modification within 24 to 48 hours - same day referral
**Hyperventilation**

Hyperventilation (Table 7) is characterized by anxiety-related dyspnea and tachypnea. Cerebral hypoxia leads to prolonged inspiration (i.e., deep sighs), which result in low CO₂ concentration and elevated arterial pH (respiratory alkalosis). Hyperventilation syndrome is common in young women. Predisposing factors include pain, and personal and environmental stress. Other causes include cardiopulmonary disease (e.g., cardiogenic shock, COPD, pulmonary edema), and central nervous system stimulants (e.g., drugs, cola, coffee, tea).

<table>
<thead>
<tr>

</tr>
<tr>
<td><strong>Emergency response:</strong></td>
</tr>
<tr>
<td>- Place patient in an upright or semi-reclining position</td>
</tr>
<tr>
<td>- Instruct the patient to take in a shallow breath and hold it as long as possible</td>
</tr>
<tr>
<td>- Repeat this sequence 6 to 10 times</td>
</tr>
<tr>
<td>- Alternatively, have patient rebreathe expired air from a paper bag – DO NOT ADMINISTER OXYGEN</td>
</tr>
<tr>
<td>- If patient is not responding</td>
</tr>
<tr>
<td>- Activate EMS</td>
</tr>
<tr>
<td>- Monitor vital signs</td>
</tr>
<tr>
<td>- If at any time the patient becomes unresponsive, no normal breathing, and no palpable pulse consider the diagnosis of cardiac arrest</td>
</tr>
<tr>
<td>- Immediate CPR and defibrillation congruent with current recommendations</td>
</tr>
<tr>
<td><strong>Nota bene:</strong></td>
</tr>
<tr>
<td>- Signs of recovering: breathing returns to normal</td>
</tr>
<tr>
<td>- Signs of deterioration: vital signs unstable</td>
</tr>
<tr>
<td>- Anxiety, often precipitated by personal or environmental stress, is the most common predisposing factor associated with hyperventilation, these patients respond well to pre-operative sedation</td>
</tr>
<tr>
<td>- Hypoxia, associated with cardiopulmonary disease, may also cause hyperventilation. Patients who relate a history of hyperventilation secondary to a medical condition (other than anxiety) should not receive pre-operative sedation</td>
</tr>
</tbody>
</table>
**Ventilation Failure**

Ventilation failure (Table 8) is defined as a rise in CO\textsubscript{2} concentration when alveolar ventilation either falls or fails to respond adequately to increased CO\textsubscript{2} production. The most common causes are acute exacerbation of asthma and COPD. Asthma is diffuse airway inflammation caused by household (dust mites, pets) and environmental (pollens) allergens in genetically susceptible patients resulting in reversible bronchoconstriction. COPD (chronic bronchitis, emphysema) is a reversible airway obstruction caused by an inflammatory response to toxins, e.g., cigarette smoke.

Table 8. Ventilation Failure.

<table>

<tr>
<td>- Anxiety, restlessness, agitation</td>
</tr>
<tr>
<td>- Pallor or cyanosis of the lips</td>
</tr>
<tr>
<td>- Noticeable use of the accessory muscles of respiration</td>
</tr>
<tr>
<td>- Patient may become confused and lethargic</td>
</tr>
<tr>
<td>- Respiratory failure (in cases of severe exacerbation)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Emergency response:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Place patient in an upright position</td>
</tr>
<tr>
<td>- Administer a short acting beta\textsubscript{2} agonist bronchodilator</td>
</tr>
<tr>
<td>- Two to 4 puffs of albuterol by metered-dose inhaler (up to 3 times 20 minutes apart)</td>
</tr>
<tr>
<td>- Administer oxygen</td>
</tr>
<tr>
<td>- Patients with asthma do not need O\textsubscript{2} unless the O\textsubscript{2}sat is &lt;90% as measured by a pulse oximeter</td>
</tr>
<tr>
<td>- 2 to 4 L/minute by nasal cannula</td>
</tr>
<tr>
<td>- Patients with COPD require O\textsubscript{2} supplementation, even those who do not need it chronically</td>
</tr>
<tr>
<td>- 2 L/minute by nasal cannula (higher levels of O\textsubscript{2} may worsen respiratory failure)</td>
</tr>
<tr>
<td>- If patient’s condition deteriorates</td>
</tr>
<tr>
<td>- Activate EMS</td>
</tr>
<tr>
<td>- Monitor vital signs</td>
</tr>
<tr>
<td>- If at any time the patient becomes unresponsive, no normal breathing, and no palpable pulse consider the diagnosis of cardiac arrest</td>
</tr>
<tr>
<td>- Immediate CPR and defibrillation congruent with current recommendations</td>
</tr>
</tbody>
</table>

**Nota bene:**

- Signs of recovery: the rate and character of breathing returns to normal
- Signs of deterioration: no improvement in the rate and character of breathing, increased cyanosis
- When ventilating a patient, squeeze the bag only until resistance is felt or the chest starts to rise and allow time for expiration
  - Attempting to ventilate with large volumes of air or too rapidly will increase "air-trapping" and may lead to pneumothorax
- Patients with a particularly severe ongoing asthma attack (status asthmaticus) who do not respond to usual treatment may progress to acute respiratory arrest and death
**Pruritus, Urticaria, and Angioedema**

Pruritus or itching (Table 9) is a dermal reaction to diverse stimuli, including light touch, vibration, wool fibers, and a number of chemical mediators. Histamine, released by mast cells is one of the most significant chemical mediators. Pruritus is a common symptom of primary skin diseases including allergic contact dermatitis. Less commonly it reflects a systemic reaction to drugs (e.g., NSAIDs, penicillin, and opioids) and other allergens.

Urticaria (Table 9) is a reaction to vasoactive substances (e.g., histamine) released by mast cells in the superficial dermis resulting in intradermal edema caused by capillary and venous vasodilation. The process could be an IgE-mediated type I hypersensitivity reaction; direct non-immune-mediated-activation of mast cells by drugs; drug-induced cyclooxygenase inhibition that activates mast cells by poorly understood mechanisms; or caused by stress and anxiety.

Angioedema (Table 9) is anaphylaxis of the subcutaneous tissues. It results from mast cell and basophil activation in the deeper dermis and subcutaneous tissues and is pathogenically related to urticaria which occurs at the epidermal-dermal junction. The causes of acute angioedema, which may be accompanied by pruritus and urticaria, include drugs and other allergens. Chronic angioedema is mostly idiopathic, rarely IgE mediated, and some cases are hereditary.

Table 9. Pruritus, Urticaria, and Angioedema.

</tbody>
</table>
**Table 9. Pruritus, Urticaria, and Angioedema. (continued)**

**Emergency response:**
- Stop exposure precipitating agent
  - Pruritus
    - Generalized
      - Administer oral diphenhydramine (an H1-receptor antagonist)
        - 25 to 50 mg, four times daily until symptoms subside
    - Acute urticaria
      - Administer oral diphenhydramine (an H1-receptor antagonist)
        - 25 to 50 mg, four times daily until symptoms subside
    - Acute angioedema
      - Mild angioedema
        - Administer diphenhydramine (an H1-receptor antagonist)
          - 25 to 50 mg, four times daily until symptoms subside
      - Severe angioedema
        - Administer prednisone
          - 30 to 40 mg, by mouth, once a day, until symptoms subside
        - Pharyngeal or laryngeal edema with stridor and wheezing
          - Activate EMS
            - Immediately administer epinephrine 1:1000
              - Adult: epinephrine (EpiPen), 0.3 mg, IM (anterolateral thigh)
              - Child: epinephrine (EpiPen Jr), 0.15 mg, IM (anterolateral thigh)

**Nota bene:**
- Signs of recovery: signs and symptoms subside
- Signs of deterioration: progressive angioedema, stridor, wheezing and other evidence of respiratory distress

**Anaphylaxis**
Anaphylaxis (Table 10) is a Type I hypersensitivity reaction. Initial exposure to an allergen results in antigen-specific antibody production dominated by the immunoglobulin E (IgE) isotype. Following re-exposure, IgE antibodies bind to mast cells and basophils associated with mucosal and epithelial tissues. The simultaneous binding of an antigen to adjacent IgE molecules fixed to Fc receptors triggers degranulation of mast cells and basophils resulting in the release of histamine, leukotrienes, prostaglandins, chemokines, enzymes and cytokines in target tissues.
### Delayed Hypersensitivity Reaction

Delayed hypersensitivity or Type IV reactions (Table 11) are T-cell-mediated, i.e., specifically sensitized CD4+ T-lymphocytes initiate the reactions. Sensitization develops slowly requiring repeated exposures to a specific allergen. Once sensitized, upon reexposure immunologically committed lymphocytes react with the allergen (antigen) and damage tissue by direct toxic effects or through the release of cytokines, which activate eosinophils, monocytes, neutrophils, and macrophages and killer cells.

**Table 10. Anaphylaxis.**

<table>
<thead>
<tr>

</tbody>
</table>
Seizures are a group of neurological disorders caused by excessive discharge of cerebral neurons. They may lead to focal (motor, sensory (somatic, visual, auditory, olfactory); psychomotor (automatisms, psychical); or generalized (myoclonic, absence, and tonic-clonic or grand mal (Table 12) seizures. The cause may be genetic; or head trauma, hypoxia, infection (fever) pregnancy, drug or alcohol overdose or withdrawal, sensory input (e.g., sound, light, touch, and smell), hypoglycemia, circulatory disturbances, degenerative disorders, and tumors.
**Table 12. Tonic-clinic (grand mal) Seizure.**

**Prevention:**
- Identify at-risk patient
  - Eliminate known causative or precipitating factors (if possible)
  - Confirm compliance with anticonvulsant chemotherapy
  - Reduce anxiety
  - Ensure profound local anesthesia
    - Use local anesthetic agents containing a vasoconstrictor congruent with the patient’s functional capacity

**Signs and symptoms:**
- Aura phase
  - Visual and auditory disturbances
  - Dizziness
- Sudden loss of consciousness
  - Initial convulsions explosively force air out of the lungs, resulting in the epileptic “cry”
  - Generalized motor tonic-clonic seizures follow this eerie, birdlike scream
    - The tonic component is characterized by opisthotonus, the person is forced into an arched position when the violent spasm of all body musculature pulls his back muscles
      - Arching of the back causes convexity in the ventral body region
    - The clonic component is characterized by alternating contraction and relaxation of all muscles
      - Tongue-biting
      - Increased salivation
      - Incontinence
      - Hyperventilation
- Postictal depression of motor and sensory function
  - Fatigue, mental confusion, and respiratory depression

**Emergency response:**
- Place patient in a supine position
  - Protect patient from injury
    - Guide the extremities during seizure, but do not restrain
  - After the seizure is complete
    - Suction oral cavity if needed
    - Position patient on his/her side (recovery position)
    - Administer oxygen
      - 4 to 6 L/minute by nasal cannula
    - Monitor vital signs
      - If at any time the patient becomes unresponsive, no normal breathing, and no palpable pulse consider the diagnosis of cardiac arrest
        - Activate EMS
          - Immediate CPR and defibrillation congruent with current recommendations

**Nota bene:**
- Signs of recovery: patient regains consciousness, respiration returns to normal
- Signs of deterioration: unconsciousness persists, respiratory depression progressing to respiratory arrest
**Cerebrovascular Accident**

Cerebrovascular accident or stroke (Table 13) is a syndrome associated with the interruption of blood supply to a portion of the brain causing neurologic deficit. Most commonly, a stroke is secondary to an evolving blood clot associated with atherosclerosis that progressively blocks a cerebral artery. Alternatively, it may be due to an embolus that lodged in a cerebral artery obstructing blood flow or result from subarachnoid or intracerebral hemorrhage into brain tissue. Stroke-like symptoms lasting less than 1 hour are termed transient ischemia attacks (TIA).

</table>
Local Anesthetic Toxicity
Local anesthetics (LAs) are nonselective voltage-gated sodium channel blockers. This nonselective blockade is not only the source of LAs' efficacy in blocking action potentials in Aδ and C fibers, but it is also responsible for LAs toxic properties related to the blockade of other sensory, motor, and autonomic fibers. Toxic reactions (Table 14) may result from (1) excessive dosage, (2) repeated doses, (3) rapid absorption, (4) unintentional intravascular injection, (5) low plasma protein binding, and (5) slow metabolism or elimination of the LA or its metabolites.

**Table 14. Local Anesthetic Toxicity.**

**Prevention:**
- Determine dosage
  - Based on weight
    - mg of drug per pound of body weight
  - If patient weighs ≥150 lbs.
    - No more than maximum recommended dose (MRD)
  - The dose of local anesthetic agent containing a vasoconstrictor congruent with the patient's functional capacity

**Signs and symptoms:**
- Nausea, vomiting
- Constriction of pupils (miosis)
- Drooling, lethargy, sedation, unconsciousness, coma
- Respiratory depression
  - Respiratory arrest
- Depressed cardiac conduction, excitability, and contractility
  - Ventricular arrhythmias
  - Atrioventricular block
  - Cardiac arrest

**Emergency response:**
- Place patient in a supine position
  - Administer oxygen
    - 4 to 6 L/min by nasal cannula
  - Activate EMS
  - Monitor vital signs
    - If at any time the patient becomes unresponsive, no normal breathing, and no palpable pulse consider the diagnosis of cardiac arrest
    - Immediate CPR and defibrillation congruent with current recommendations

**Nota bene:**
- Signs of recovery: mental state improves, vital signs return to baseline values
- Signs of deterioration: altered consciousness progressing to coma, vital signs labile
- Accurate statistics on local anesthetic-related deaths are not readily available
  - Estimates range from 1 in 1.4 million to 1 in 45 million
Summary
Preparedness in emergency medicine mandates didactic and clinical training in emergency medicine, periodic office emergency drills, and maintaining basic emergency drugs and equipment. Education and hands-on training should include issues related to prevention, recognition, and emergent-setting-appropriate management of medical emergencies with emphasis on the importance of performing a primary and a secondary survey.
Course Test Preview
To receive Continuing Education credit for this course, you must complete the online test. Please go to: www.dentalcare.com/en-us/professional-education/ce-courses/ce516/start-test

1. All of the following statements related to medical emergencies in oral healthcare settings are correct EXCEPT which one?
   a. Diagnostic activities should be effective to establish a database that identifies those patients at-risk who may experience a medical emergency.
   b. Available data on the types and incidence of medical emergencies in oral healthcare indicate that the rate of medical emergencies per dentist per year is quite high.
   c. At a minimum, in the event of a life-threatening medical emergency, OHCP must feel comfortable to perform BLS techniques to stabilize the patient until EMS arrives.
   d. It must be emphatically stated that advanced life support (ALS) activities should not be attempted without sufficient training and maintenance of skills.

2. All of the following statements related to procedure-specific risk factors are correct EXCEPT which one?
   a. Every procedure elicits a stress-response, i.e., “surgical stress,” characterized by physiological changes accompanied by psychological reactions.
   b. The magnitude of surgical stress is unrelated to the severity of tissue trauma, duration of the procedure, volume of blood loss, fluid shifts, and changes in core body temperature.
   c. Procedure-related surgical stress can be classified as high, intermediate, and low with estimated rates of associated major medical events of >5%, 1-5%, and <1%, respectively.
   d. With low surgical stress, e.g., dental procedures, the risk of a major medical event is negligible unless strong patient-specific risk factors are present.

3. Which of the following statements is correct with respect to a determination of patient-specific risk factors?
   a. Identification of patient-specific risk factors is predicated on data obtained from the physical evaluation, i.e., medical history and physical examination.
   b. The medical history should also seek to determine the patient's functional capacity.
   c. Critically, the physical examination must also include a determination of the patient's baseline vital signs.
   d. All of the above.

4. All of the following statements are correct with respect to functional capacity EXCEPT which one?
   a. FC relates to a person's functional reserve, which correlates well with maximum oxygen uptake during treadmill testing.
   b. The inability of a person to climb two flights of stairs or to run a short distance indicates poor functional capacity (< 4 METs).
   c. For a patient with a history of CAD who is asymptomatic and runs 30 minutes daily the risk of a medical emergency is predictable high.
   d. A validated method to determine FC is predicated on a person's ability to perform a spectrum of common daily activities.
5. **Which of the following statement related to the ASA PS classification system is correct?**
The ASA PS classification system ___________.
   a. is predicated on patient-specific risk factors identified during the physical evaluation  
   b. provides a practical method to quantify perioperative risk for patients undergoing surgical  
      (and by extension dental) procedures  
   c. defines ASA PS II as a patient with well-controlled mild systemic disease affecting one organ  
      system and no substantive functional limitations, i.e., good functional capacity  
   d. All of the above.

6. **Which of the following statements is correct with respect to the risk of major medical events associated with ASA FS IV?**
   a. Minimal risk  
   b. No immediate risk  
   c. Imminent risk  
   d. Possible risk

7. **Being prepared to respond to a major medical event in oral healthcare settings includes developing a medical emergency team and ___________.**
   a. knowing what to look for, i.e., familiarity with predisposing factors and signs and symptoms  
      of medical emergencies  
   b. being alert, i.e., looking for evidence of distress or adverse reactions, particularly when drugs  
      are being administered to the patient  
   c. regularly checking the status of emergency drugs and other equipment  
   d. All of the above.

8. **When faced with an emerging medical event, three hierarchical steps (i.e., the primary survey) must be implemented in every situation to identify which of the following problems?**
   a. Obstructed airway  
   b. Respiratory arrest  
   c. Cardiac arrest  
   d. All of the above.

9. **Which of the following statements correctly reflect a patient’s level of consciousness as determined during the primary survey?**
   a. An alert patient is awake and speaks.  
   b. A disoriented patient may moan, cry, or make other sound, but responds to verbal and/or painful stimuli, i.e., moves.  
   c. An unresponsive patient is silent and does not respond to verbal and a painful stimulus, i.e., the patient is unconscious.  
   d. All of the above.

10. **When the patient is unresponsive, as determined during the primary survey ___________.**
    a. place the patient in the dental chair in a supine position on a firm, flat board (e.g., EMS board) to allow for adequate compressions later  
    b. summon the office emergency team  
    c. activate emergency medical services (EMS)  
    d. All of the above.
11. **Which of the following statements is correct with respect to the status of the airway and actions to be taken during the primary survey?**
   a. If the patient is responsive (i.e., alert and talking, even in a whisper) the airway is open (at least partially) at this time.
   b. If the patient is unresponsive (i.e., does not respond to verbal and painful stimuli) evaluate airway and the airway is not open, it may be due to relaxation of the soft tissues of the oropharynx - perform head-tilt/chin-lift.
   c. If obstruction is caused by foreign material it must be cleared - suction thick, frothy, bloody saliva and vomitus; foreign object must be removed.
   d. All of the above.

12. **During the primary survey, ___________.**
   a. simultaneously, see if the patient's chest rises and falls, listen for escaping air, feel the airflow against the side of your cheek; and palpate the carotid artery
   b. if the breathing is not normal, but the patient has definite pulse initiate rescue breathing (1 breath every 5-6 seconds (10 to 12 breaths/min.)
   c. check pulse every 2 minutes - if no pulse, begin cardiopulmonary resuscitation (CPR) and prepare for automated external defibrillation (AED)
   d. All of the above.

13. **During the primary survey, if there is no breathing or only agonal breaths (i.e., isolated or infrequent gasping) and no pulse begin CPR (cycles of 30 compressions and 2 breaths) and ___________.**
   a. while continuing with CPR, turn on AED and apply AED pads - when the AED is ready to analyze the heart rhythm, ensure that everyone, including the rescuer performing CPR, is clear of the patient
   b. if the AED advises that a shock is not indicated resume CPR immediately until prompted by AED to allow rhythm check (about 2 minutes)
   c. if the AED advises that a shock is indicated press the shock button and resume CPR immediately until prompted by AED to allow rhythm check (about 2 minutes)
   d. All of the above.

14. **For each minute CPR and defibrillation is delayed, the patient's chances of survival is reduced by 7 to 10 percent.**
   a. True
   b. False

15. **All of the following statements related to airway obstruction due to a foreign object are correct EXCEPT which one?**
   a. A conscious patient who is clutching the throat is showing the universal sign of choking - encourage the patient to cough forcefully until he/she can breathe normally.
   b. If the coughs become weak and ineffective, place the patient in a supine position and deliver quick, upward abdominal thrusts until the object is forced out.
   c. If the patient becomes unresponsive, immediately begin CPR with chest compressions and make sure an AED is readily available.
   d. Each time the airway is opened to give ventilations, look for any visible objects in the oropharynx - if a foreign object is not visible, perform a blind finger sweep.
16. **All of the following statements related to the secondary survey are correct EXCEPT which one?**
   a. If the patient is conscious and communicative, proceed with the secondary survey.
   b. Before determining the patient's the blood pressure, reassess the pulse rate and character and the rate and character of respiration.
   c. During the secondary survey correlate signs and symptoms associated with the patient's chief complaint to a specific organ or body system.
   d. The secondary survey is to identify problems that are not immediately life-threatening (e.g., hypoglycemia, angina pectoris, ventilation failure), but require timely stabilization.

17. **Which of the following statements related to medical emergencies within the context to the secondary survey is correct?**
   a. Physical signs and symptoms are produced by physical causes and must be recognized before a physical problem can be diagnosed and treated.
   b. Without at least a presumptive or working diagnosis there is nothing to treat.
   c. Based on symptoms analysis, medical emergencies can be characterized as altered consciousness; chest pain; and ventilatory, allergic (pruritus, urticaria, angioedema), neurogenic (i.e., sensory, affective, motor), and toxic events.
   d. All of the above.

18. **Which of the following statement related to syncope is correct?**
   a. Syncope is defined as sudden brief loss of consciousness due to cerebral ischemia.
   b. In the young adult it is usually precipitated by a generalized, progressive autonomic discharge secondary to anxiety, pain, heat, or humidity.
   c. Syncope in patients over 50 years of age may likely be secondary to cardiovascular disorders (e.g., dysrhythmia, postural hypotension), hypoglycemia or cerebrovascular insufficiency.
   d. All of the above.

19. **Which of the following statements associated with syncope is correct?**
   a. Signs and symptoms associated with the cholinergic component of syncope include diaphoresis (perspiration), nausea, salivation, bradycardia, hypotension, and loss of consciousness.
   b. When the working diagnosis is syncope, place patient in Trendelenburg position, i.e., head and chest slightly below a line parallel to the floor and feet slightly elevated.
   c. Emergency responses to syncope include the administration of oxygen, 4 to 6 L/min by nasal cannula, and stimulation of cutaneous reflexes.
   d. All of the above.

20. **All of the following statements related to postural hypotension are correct EXCEPT which one?**
   a. Postural hypotension is defined as a decline of ≥20 mm Hg in the systolic BP, and/or a decline of ≥10 mm Hg in the diastolic BP, or an increase of ≥20 beats/minute in pulse rate.
   b. Signs and symptoms of postural hypotension include a distinctive prodrome.
   c. Acute signs and symptoms include abrupt cerebral ischemia (syncope) following postural change from a supine to an upright position.
   d. Postural hypotension may be secondary to impaired homeostatic mechanisms of blood pressure regulation; age and/or cardiovascular-disease-related physiological changes; anti-hypertensive medications; and/or recent intake of food.
21. Which of the following statements related to the emergency response to postural hypotension is correct?
   a. Immediately return patient to supine position for 5-10 minutes; administer oxygen, 4 to 6 L/min by nasal cannula; and reevaluate vital signs.
   b. When vital signs return to baseline values, allow patient to assume a sitting position for at least 2 minutes; reevaluate vital signs.
   c. If vital signs are stable, allow patient to stand for 2 minutes; reevaluate vital signs; stable vital signs and alertness are signs of recovery.
   d. All of the above.

22. All of the following statements related to hypoglycemia are correct EXCEPT which one?
   a. Glucagon promotes hepatic glycogenolysis and gluconeogenesis and is a hypoglycemic agent.
   b. Hypoglycemia is defined as sustained plasma glucose level <70 mg/dL.
   c. Heavy exercise, anxiety, and infection may cause hypoglycemia.
   d. The most common cause of hypoglycemia is treatment with insulin and/or oral hypoglycemic agents and delayed, decreased, or missed meals.

23. All of the following statements related to hypoglycemia are correct EXCEPT which one?
   a. Neuroglycopenic manifestations of hypoglycemia include twitching and tremor; anxiety and nervousness; sweating, cold, clammy skin; pallor; and mydriasis.
   b. If the working diagnosis is mild hypoglycemia, i.e., the patient is conscious, able to follow commands, and can swallow administer glucose tablets (if available), otherwise a glass of fruit juice or 3 tbsp of sugar with water is acceptable.
   c. If the diagnosis is severe hypoglycemia, i.e., altered or loss of consciousness and/or seizure, activate EMS; apply a ribbon of sucrose paste (cake icing) on oral soft tissues or administer glucagon, 1 mg, IM or SL; administer oxygen, 4 to 6 L/min by nasal cannula; and monitor vital signs.
   d. Signs of recovery include improved mental state.

24. Which of the following statements related to angina pectoris is correct?
   a. Angina pectoris is an acute coronary syndromes associated with transient ischemia to the myocardium.
   b. Hypoxia (and at times anoxia) results from diseases and conditions which lead to atherosclerosis and obstruction of coronary arteries by fatty deposits that limits and/or impairs coronary blood flow.
   c. Precipitating factors that increase cardiac oxygen demand in the presence of decreased perfusion of the myocardium include physical exertion, emotional stress, cold, recent meal.
   d. All of the above.

25. Which of the following statements related to angina pectoris is correct?
   a. If the working diagnosis is angina pectoris, place patient in an upright or semi-reclining position; note the time and administer nitroglycerin, 0.4 mg, tablet or spray, SL; administer oxygen, 2 to 4 L/minute by nasal cannula; and reevaluate vital signs.
   b. In a conscious patient, chest pain lasting more than 10 minutes must be assumed to be due to unstable angina or myocardial infarction; activate EMS.
   c. Adverse reaction to nitroglycerin includes flushing, headaches, dizziness, nausea, and vomiting; syncope and paradoxical angina pectoris due to nitrate-induced vasodilation has been reported.
   d. All of the above.
26. All of the following statements related to myocardial infarction are correct EXCEPT which one?
   a. Myocardial infarction is caused by abrupt anoxia to a portion of the heart resulting in myocardial tissue necrosis.
   b. Anoxia results from conditions that lead to the formation of atherosclerotic plaques, which in later stages become disrupted and contribute to thrombus formation.
   c. Atherosclerotic plaques and thrombi impair blood flow to large and medium-sized veins of the heart.
   d. History of cardiovascular diseases, diabetes mellitus, and cerebrovascular disease increases the overall risk of perioperative MI.

27. All of the following statements are correct with respect to myocardial infarction EXCEPT which one?
   a. If the working diagnosis is myocardial infarction, place patient in an upright or semi-reclining position; activate EMS; administer oxygen, 6 L/min by nasal cannula; and encourage patient to chew an adult aspirin, 325 mg, unless otherwise contraindicated.
   b. If at any time the patient becomes unresponsive, no normal breathing, and no palpable pulse consider the diagnosis of cardiac arrest and initiate immediate CPR and defibrillation congruent with current recommendations.
   c. Patient denial may minimize symptoms and elderly and diabetic patients have a higher incidence of silent MI characterized by vague symptoms of shortness of breath, epigastric distress, hypotension, and altered mental state.
   d. More than 6 months should elapse after a MI before elective noncardiac procedures, e.g., elective dental care is considered.

28. All of the following statements related to hypertensive emergency are correct EXCEPT which one?
   a. Hypertension is defined as a blood pressure (BP) ≥140/90 mm Hg.
   b. Hypertensive emergency is defined by a BP ≥180/110 mm Hg and signs and symptoms of severely elevated BP.
   c. Hypertensive emergency is unlikely with the administration of sympathomimetic drugs such as high doses of epinephrine.
   d. The mechanisms that lead to severely elevated BP appear to be related to a failure of normal autoregulatory function resulting in increased vascular resistance caused by endogenous vasopressors in patients with unrecognized or under-treated hypertension.

29. All of the following statements related to hypertensive emergency or urgency are correct EXCEPT which one?
   a. If the working diagnosis is hypertensive emergency, place patient in an upright or semi-reclining position; activate EMS; administer oxygen, 4 to 6 L/min by nasal cannula; and monitor vital signs.
   b. In a hypertensive emergency in the oral health care setting, the BP should be promptly lowered to decrease the mean arterial pressure (MAP) to prevent cerebral ischemia.
   c. If the working diagnosis is hypertensive urgency (BP ≥180/110 mm Hg, patient is asymptomatic), medical evaluation and risk modification is indicated within 24 to 48 hours.
   d. Untreated hypertensive emergency can lead to altered mental state, chest pain (myocardial ischemia, infarction, or aortic dissection), seizure, cerebral hemorrhage, coma, and death.
30. All of the following statements related to hyperventilation are correct EXCEPT which one?
   a. Hyperventilation is characterized by cerebral hypoxia that leads to prolonged inspiration (i.e., deep sighs), which result in low CO2 concentration.
   b. Predisposing factors in young people include pain, and personal and environmental stress.
   c. Hyperventilation syndrome is especially common in young men.
   d. Hyperventilation may be secondary to cardiopulmonary disease (e.g., cardiogenic shock, COPD, pulmonary edema), and central nervous system stimulants (e.g., drugs, cola, coffee, tea).

31. All of the following statements related to hyperventilation are correct EXCEPT which one?
   a. If the working diagnosis is hyperventilation, place patient in an upright or semi-reclining position; instruct the patient to take in a shallow breath and hold it as long as possible; repeat this sequence 6 to 10 times.
   b. If the working diagnosis is hyperventilation, place patient in an upright or semi-reclining position and administer oxygen, 4 to 6 L/min by nasal cannula.
   c. Signs and symptoms of hyperventilation include light-headedness and dizziness, paresthesia, burning or prickling feeling of the face and extremities tightness or pain in the chest, and syncope.
   d. Tonic muscle spasm and tetani can occur because with severe respiratory alkalosis.

32. All of the following statements are correct with respect to ventilation failure EXCEPT which one?
   a. Ventilation failure is defined as a rise in CO₂ concentration when alveolar ventilation either falls or fails to respond adequately to increased oxygen.
   b. The most common causes are acute exacerbation of asthma and chronic obstructive pulmonary disease (COPD).
   c. Asthma is a diffuse airway inflammation in response to household (dust mites, pets) and environmental (pollens) allergens in genetically susceptible patients resulting in reversible bronchoconstriction.
   d. COPD is a reversible airway obstruction caused an inflammatory response to toxins, e.g., cigarette smoke.

33. All of the following statements are correct with respect to ventilation failure EXCEPT which one?
   a. Signs and symptoms of ventilation failure include coughing, wheezing, shortness of breath (dyspnea); anxiety, restlessness, agitation; pallor or cyanosis of the lips; noticeable use of the accessory muscles of respiration; and respiratory failure.
   b. If the working diagnosis is ventilation failure, place patient in an upright position; administer a short acting beta₂ agonist bronchodilator, two to 4 puffs of albuterol by metered-dose inhaler (up to 3 times 20 minutes apart).
   c. Patients with asthma do not need O₂ unless the O₂sat is <90% as measured by a pulse oximeter, 2 to 4 L/min by nasal cannula.
   d. Patients with COPD must not be given O₂ supplementation, as higher levels of O₂ may worsen respiratory failure.
34. Which of the following statements is correct with respect to pruritus, urticaria, or angioedema?
   a. Histamine, released in response to various stimuli, is one of the most significant chemical mediators associated with pruritus.
   b. Urticaria is the result of vasoactive substances (e.g., histamine) released by mast cells in the superficial dermis resulting in intradermal edema caused by capillary and venous vasodilation.
   c. Angioedema is considered anaphylaxis of the subcutaneous tissues and results from mast cell and basophil activation in the deeper dermis and subcutaneous tissues.
   d. All of the above.

35. Which of the following statements is correct with respect to the appropriate emergency response to pruritus, urticaria, or angioedema?
   a. If the working diagnosis is generalized pruritus, urticaria, or mild angioedema, stop exposure to suspected precipitating agents and administer oral diphenhydramine (an oral H1-receptor antagonist), 25 to 50 mg, four times daily.
   b. If the working diagnosis is severe angioedema stop exposure to suspected precipitating agents and administer prednisone 30 to 40 mg, once a day.
   c. If the working diagnosis is severe angioedema with oropharyngeal and/or laryngeal edema with stridor and wheezing stop exposure to suspected precipitating agents, activate EMS, and administer epinephrine (1:1000).
   d. All of the above.

36. Which of the following statements related to anaphylaxis is correct?
   a. Anaphylaxis is a type I hypersensitivity reaction – initial exposure to an allergen results in antigen-specific antibody production dominated by the immunoglobulin E (IgE) isotype.
   b. Following re-exposure, IgE antibodies bind to mast cells and basophils associated with mucosal and epithelial tissues.
   c. The simultaneous binding of an antigen to adjacent IgE molecules fixed to Fc receptors triggers degranulation of mast cells and basophils resulting in the release of histamine, leukotrienes, prostaglandins, chemokines, enzymes and cytokines in target tissues.
   d. All of the above.

37. All of the following statements related to the emergency response to anaphylaxis are correct EXCEPT which one?
   a. The onset of anaphylaxis is 1 to 15 minutes following exposure to a specific allergen characterized by pruritus, urticaria, angioedema; coughing, stridor, dyspnea, wheezing; agitation, flushing, palpitation; unresponsiveness, convulsion; and hypotension, and cardiogenic shock.
   b. If the working diagnosis is anaphylaxis, place patient in a supine position; activate EMS; immediately administer epinephrine 1:1000: adult - epinephrine (EpiPen), 0.3 mg, IM (anterolateral thigh), child - epinephrine (EpiPen Jr), 0.15 mg, IM (anterolateral thigh).
   c. If a patient with anaphylaxis does not respond to an initial dose of epinephrine and the arrival of EMS will exceed 30 minutes, a repeat dose may be administered.
   d. If at any time a patient with anaphylaxis becomes unresponsive, no normal breathing, and no palpable pulse consider the diagnosis of cardiac arrest and initiate CPR and defibrillation congruent with current recommendations.
38. **Which of the following statements related to Type IV delayed hypersensitivity reactions is correct?**
   a. Type IV, delayed hypersensitivity reactions are closely related to cellular immunity in that specifically sensitized CD4+ T-lymphocytes initiate the reaction.
   b. Once sensitized, upon reexposure immunologically committed lymphocytes react with the allergen (antigen) and release cytokines (i.e., lymphokines).
   c. Lymphokines activate macrophages resulting in the release of histamine, leukotrienes, prostaglandins, chemokines, enzymes and cytokines in target tissues.
   d. All of the above.

39. **All of the following statements are correct with respect to delayed hypersensitivity reaction EXCEPT which one?**
   a. Identify drugs and other potential allergens to which the patient may have been exposed to in the clinical process.
   b. Verify that the onset of signs and symptoms was 6 to 48 hours after the initiation of pharmacological or clinical intervention.
   c. In the absence of respiratory distress prescribe diphenhydramine hydrochloride, 25 to 50 mg, PO, q.i.d; and arrange supervision of patient for at least 6 hours.
   d. Instruct patient or caretaker that if wheezing develops to call you immediately.

40. **Which of the following statements related to seizures is correct?**
   a. Seizures are a group of neurological disorders caused by excessive discharge of cerebral neurons.
   b. Seizures may lead to focal (motor, sensory (somatic, visual, auditory, olfactory), or psychomotor (automatisms, psychical); or generalized myoclonic, absence (petit mal), and tonic-clonic or grand mal seizures.
   c. The cause of seizure may be genetic; or head trauma, hypoxia, infection (fever) pregnancy, drug or alcohol overdose or withdrawal, sensory input (e.g., sound, light, touch, and smell), hypoglycemia, circulatory disturbances, degenerative disorders, and tumors.
   d. All of the above.

41. **Which of the following statements related to the emergency response to grand mal seizure is correct?**
   a. Place patient in a supine position; protect patient from injury, i.e., guide the extremities during seizure, but do not restrain.
   b. After the seizure is complete suction oral cavity if needed; position patient on his/her side (recovery position); administer oxygen, 4 to 6 L/min by nasal cannula.
   c. Monitor vital signs; if at any time the patient becomes unresponsive, no normal breathing, and/or no palpable pulse activate EMS.
   d. All of the above.

42. **Which of the following statements related to stroke is corrects?**
   a. Most commonly, a stroke is secondary to an evolving blood clot associated with atherosclerosis that progressively blocks a cerebral artery.
   b. Stroke may be due to an embolus that lodged in a cerebral artery obstructing blood flow or result from subarachnoid or intracerebral hemorrhage into brain tissue.
   c. Stroke-like symptoms lasting less than 1 hour are termed transient ischemia attacks (TIA).
   d. All of the above.
43. All of the following statements related to the emergency response to a case of suspected stroke are correct EXCEPT which one?
   a. Ask patient to smile, abnormal: one side of face does not move at all.
   b. Ask patient to raise both arms, abnormal: one arm drifts compared to the other.
   c. Ask the patient to repeat “you can’t teach an old dog new tricks,” abnormal: slurred or inappropriate words or mute.
   d. If the patient shows all three of the above abnormal symptoms, activate EMS.

44. Which of the following statements is correct with respect to local anesthetic toxicity?
   a. Nonselective voltage-gated sodium channel blockade is responsible for LA's toxic properties.
   b. Most commonly, toxic reactions result from (1) excessive dosage, (2) repeated doses, (3) rapid absorption, and (4) unintentional intravascular injection.
   c. Toxic reactions may be due to low plasma protein binding, and slow metabolism or elimination of the LA or its metabolites.
   d. All of the above.

45. Which of the following statements is correct with respect to the emergency response to local anesthetic toxicity?
   a. Place patient in a supine position; administer oxygen, 4 to 6 L/min by nasal cannula; activate EMS; monitor vital signs.
   b. Signs of recovery: mental state improves, vital signs return to baseline values.
   c. Signs of deterioration: altered consciousness progressing to coma; progressive respiratory and/or cardiac depression.
   d. All of the above.
