Don’t insert percutaneous feeding tubes in individuals with advanced dementia. Instead, offer oral assisted feedings.

Don’t use sliding scale insulin (SSI) for long-term diabetes management for individuals residing in the nursing home.

Don’t obtain urine tests until clinical criteria are met.

Don’t prescribe antipsychotic medications for behavioral and psychological symptoms of dementia (BPSD) in individuals with dementia unless management of potential underlying causes fails to respond to best treatment practices. Only use for symptoms that severely impact quality of life or safety from self and/or others, in lowest dose possible and with frequent re-assessment for necessity and efficacy.

These items are provided solely for informational purposes and are not intended as a substitute for consultation with a medical professional. Patients with any specific questions about the items on this list or their individual situation should consult their physician.
Don’t routinely prescribe lipid-lowering medications in individuals with a limited life expectancy.

Hypercholesterolemia is an important risk factor for all-cause mortality, coronary heart disease mortality, hospitalization for myocardial infarction or unstable angina in persons with known CAD (i.e., secondary prevention) and among those up to age 75 years without prior CV events (i.e., primary prevention), for whom statins may have additional benefits. The strength of association between cholesterol and events is weaker in those with advanced age, and competing risks play a greater role particularly among those with frailty, comorbidity, physical or cognitive decline, or limited life expectancy. Both primary and secondary prevention should aim to achieve a net-benefit, balancing potential harm(s) of polypharmacy and side effects, and in some cases discontinuation may be reasonable. However, discontinuation of secondary prevention statin therapy should only be done after careful discussion of risk/benefit. Among high risk patients (i.e. with diabetes or multiple CV risk factors), without functional decline in whom there is a benefit to continuation of therapy but who develop side effects, consideration could be given to dose reduction.

Don’t place an indwelling urinary catheter to manage urinary incontinence.

Bacteremia are most commonly caused by UTIs in the post-acute and long-term care (PALTC) setting, the majority of which are catheter-related. The federal Healthcare Infection Control Practices Advisory Committee (HICPAC) recommends minimizing urinary catheter use and duration of use in all patients. Specifically, HICPAC recommends not using a catheter to manage urinary incontinence in the PALTC setting. Appropriate indications for indwelling urinary catheter placement include acute retention or outlet obstruction, to assist in healing of deep sacral or perineal wounds in patients with urinary incontinence, and to provide comfort at the end of life if needed.

Don’t recommend screening for breast, colorectal or prostate cancer if life expectancy is estimated to be less than 10 years.

Many patients residing in the LTC setting are elderly and frail, with multimorbidity and limited life expectancy. Use of screening tests in patients with the shortest life expectancies is common even though they are the least likely to survive long enough to benefit from the intervention and the most likely to suffer complications of the intervention. Preventive cancer screenings have both immediate and longer term risks (e.g., procedural and psychological risks, false positives, identification of cancer that may be clinically insignificant, treatment-related morbidity and mortality). Benefits of cancer screening occur only after a lag time of 10 years (colorectal or breast cancer) or more (prostate cancer). Discussing the lag time (“When will it help?”) with patients is at least as important as discussing the magnitude of any benefit (“How much will it help?”), and it is critical to elicit whether the patient’s values and goals include pursuing a treatment if an abnormality is found. Prostate cancer screening by prostate-specific antigen testing is not recommended for asymptomatic patients because of a lack of life-expectancy benefit. One-time screening for colorectal cancer in older adults who have never been screened may be cost-effective; however, it should not be considered after age 85 and for most LTC patients older than 75 the burdens of screening likely outweigh any benefits.

Don’t obtain a C. difficile toxin test to confirm “cure” if symptoms have resolved.

Patients residing in PALTC are particularly at risk for CDI due to advanced age, frequent hospitalizations and frequent antibiotic exposure. Only symptomatic patients with diarrhea should be tested for C. difficile. Furthermore, C. difficile tests may remain positive for as long as 30 days after symptoms have resolved. False positive “test-of-cure” specimens may complicate clinical care and result in additional courses of inappropriate anti-C. difficile therapy as well as prolonged isolation. To limit the spread of C. difficile, care providers in the PALTC setting should concentrate on early detection of symptomatic patients and the consistent use of proper infection control practices including the use of gloves, hand hygiene (with an alcohol-based hand rub or soap and water), contact precautions, and environmental cleaning with a sporicidal agent.

Don’t recommend aggressive or hospital-level care for frail individuals without a clear understanding of the individual’s goals of care and the possible benefits and burdens.

Hospital-level care has known risks, including delirium, infections, side effects of medications and treatments, disturbance of sleep, and loss of mobility and function. Multiple studies have shown an increase in cognitive decline following hospitalization, especially admissions involving intensive care and those in which delirium was identified. These risks are often more significant for patients in the PALTC setting, who are more likely to be frail, have multimorbidity, functional limitations, and dementia. Therefore, for some frail older adults, the balance of benefits and harms of hospital-level care may be unfavorable. To avoid unnecessary hospitalizations, care providers should engage in advance care planning by defining goals of care for the patient and discussing the risks and benefits of various interventions, including hospitalization, in the context of prognosis, preferences and indications. Patients who opt for less-aggressive treatment options are less likely to be subjected to unnecessary, unpleasant and invasive interventions and the risks of hospitalization. Advance directives such as the Physician Orders for Life Sustaining Treatment (POLST) paradigm form and Do Not Hospitalize (DNH) orders communicate a patient’s preferences about end-of-life care.
Don’t initiate aggressive antihypertensive treatment in frail individuals ≥60 years of age. For frail individuals with hypertension, multiple medical comorbidities, and limited life expectancy, use clinical judgment, incorporate patient/family preferences, and evaluate risk/benefit in deciding on medication(s) and the intensity of control.

There is strong evidence for the treatment of hypertension in older adults. Achieving a goal SBP of 150mm Hg reduces stroke incidence, all-cause mortality and heart failure, and data supports treating more aggressively to a goal SBP of <140mm Hg in community-dwelling individuals ≥75 years of age with elevated cardiovascular risk. However, more data is needed to guide treatment of hypertension in frail older adults in the post-acute and long-term care setting. Target SBP and DBP levels should be based on shared decision-making with the patient, with particular consideration of physiologic age and the presence of underlying coronary artery disease. Antihypertensive therapy may not be appropriate to initiate in some patients with severe frailty or geriatric syndromes, as moderate or high-intensity treatment of hypertension has been associated with an increased risk of serious falls and injury in frail older adults, and low BP targets have added risk for syncope in the context of dehydration, especially during periods of high ambient heat, diminished thirst sensitivity, as well as polypharmacy with other medications (Parkinson’s, etc). Using a reliable, representative method of taking blood pressures with special attention to orthostatic hypotension is important, as orthostatic hypotension has been associated with increased mortality and cardiovascular events. Careful initiation of a single agent with subsequent monitoring and evaluation for side effects can decrease the risk of adverse outcomes.

Don’t continue hospital-prescribed stress ulcer prophylaxis with Proton-Pump Inhibitor (PPI) therapy in the absence of an appropriate diagnosis in the post-acute and long-term care (PALTC) population.

In the absence of an appropriate diagnosis for the use of PPI’s long-term in PALTC populations, stop hospital prescribed medications for stress prophylaxis, as literature does not support PPI use for stress ulcer prophylaxis outside the Intensive Care Unit setting. It is important to determine the indication for use and balance potential harm versus benefit recognizing potential adverse events with long-term PPI use, including pneumonia, fracture, chronic kidney disease and bacterial infections such as Clostridiodes difficile.

Don’t order routine follow up chest imaging for post-acute and long-term care residents with community acquired pneumonia whose symptoms have resolved within 5–7 days.

Radiographic findings tend to lag behind clinical response. Obtaining routine follow up chest radiograph in patients with CAP who have responded to prescribed therapy is therefore not indicated and does not improve care outcomes. This approach is similar to that outlined by the American Thoracic Society (ATS) and Infectious Diseases Society of America (IDSA), both of whom recommend not obtaining a follow-up chest radiograph in patients whose symptoms have resolved within five to seven days.

Don’t routinely prescribe or continue sedative hypnotics such as Restoril or Ambien, diphenhydramine (Benadryl), benzodiazepines, or Serotonin Modulators (Trazadone) for long-term treatment of sleep disorders in geriatric populations. Consider the use of nonpharmacological interventions (e.g., physical activity, a regular schedule or cognitive behavioral therapy.)

Use of diphenhydramine (or other first generation antihistamines), benzodiazepines or sedative hypnotics with anticholinergic side effects should be avoided as the data suggests these drugs may cause confusion and delirium in the short term, and some have been associated with an increased risk of dementia with long-term use. These drugs are associated with a five-fold increase in adverse cognitive events, an increase in adverse psychomotor events and are associated with an increased risk of falls. The 2019 updated Beers criteria for potentially inappropriate medications for use in older adults recognized these medications as problematic.

Don’t routinely prescribe or continue acetyl cholinesterase inhibitors or N-Methyl-D-Aspartate antagonists in patients with advanced dementia.

Use of acetyl cholinesterase inhibitors in mild to moderate dementia or NMDA antagonists in moderate to severe dementia may help with Behavioral and Psychological Symptoms of Dementia (BPSD) but have not been shown to prolong life. Once an individual is institutionalized, review of the risks and benefits of the medications should be reviewed periodically and de-prescribed when no longer demonstrating benefit to the patient. Acetyl cholinesterase inhibitors can worsen anorexia and NMDA receptor agonists are not indicated with severe renal insufficiency, both of which could be present in the older population.

Don’t provide long-term opioid therapy for chronic non-cancer pain in the absence of clear and documented benefits to functional status and quality of life.

Post-acute and long-term care practitioners should prescribe opioids based on thoughtful inter-professional assessment indicating a clear indication for opioid use. Periodic review to evaluate risk factors for potential harms of long-term opioid therapy should be incorporated into the individualized plan of care. For residents on long term opioid therapy for chronic pain (not for cancer, palliative care, or end-of-life), tapering plans should be individualized and should minimize symptoms of opioid withdrawal while maximizing pain treatment. Clinicians should offer alternative behavioral therapies, non-opioid analgesics and other non-pharmacologic treatments whenever available and appropriate.
How This List Was Created (1–5)

The AMDA – The Society for Post-Acute and Long-Term Care Medicine convened a work group made up of members from the Clinical Practice Steering Committee (CPSC). Members of the CPSC include board certified geriatricians, certified medical directors, multi-facility medical directors, attending practitioners, physicians practicing in both office-based and nursing facility practice, physicians in rural, suburban and academic settings, those with university appointments, and more. It was important to AMDA that the workgroup chosen represent the core base of the AMDA membership. Ideas for the “five things” were solicited from the workgroup. Suggested elements were considered for appropriateness, relevance to the core of the specialty and opportunities to improve patient care. They were further refined to maximize impact and eliminate overlap, and then ranked in order of potential importance both for the specialty and for the public. A literature search was conducted to provide supporting evidence or refute the activities. The list was modified and a second round of selection of the refined list was sent to the workgroup for paring down to the final “top five” list. Finally, the work group chose its top five recommendations before submitting a final draft to the AMDA Executive Committee, which were then approved.

How This List Was Created (6–10)

The AMDA Clinical Practice Steering Committee acted as the Technical Expert Panel (TEP).

Phase 1 – The Clinical Practice Steering Committee (CPSC) along with the Infection Advisory Committee clinicians brainstormed an initial list of low-value clinical decisions that are under control of PALTC physicians that were thought to have a potential for cost savings.

Phase 2 – Each member of the CPSC selected five low-value tests considering the perceived contribution to cost (how commonly the item is ordered and the individual expense of the test/treatment/action), benefit of the item (scientific evidence to support use of the item in the literature or in guidelines); and highly actionable (use decided by PALTC clinicians only).

Phase 3 – A survey was sent to all AMDA members. Statements were phrased as specific overuse statements by using the word “don’t,” thereby reflecting the action necessary to improve the value of care.

Phase 4 – CPSC members reviewed survey results and chose the five items.

For more information, visit www.paltc.org.

How This List Was Created (11–15)

The AMDA Choosing Wisely project utilized procedures similar to previous workgroups.

In Phase 1 – The Clinical Practice Steering Committee (CPSC) solicited recommendations from members of the Society’s five subcommittees.

In Phase 2 – Each member of the CPSC reviewed the submitted recommendations (with the goal of selecting the best five recommendations) considering the perceived contribution to cost, benefit of the item and scientific evidence to support use of the item in the literature or in guidelines. Based on the feedback of the CPSC, the recommendations were narrowed to five, revised, and supporting evidence was added.

Phase 3 – The revised five recommendations and sources were reviewed by the CPSC for final approval, and then approved by the Board of Directors.

The mission of the ABIM Foundation is to advance medical professionalism to improve the health care system. We achieve this by collaborating with physicians and physician leaders, medical trainees, health care delivery systems, payers, policymakers, consumer organizations and patients to foster a shared understanding of professionalism and how they can adopt the tenets of professionalism in practice.

About AMDA

AMDA — The Society for Post-Acute and Long-Term Care Medicine is dedicated to excellence in patient care and provides education, advocacy, information and professional development to promote the delivery of quality post-acute and long-term care (PALTC) medicine. AMDA strives to provide cutting edge education, information, and tools on advocacy, clinical, management and technology topics that are specific to the evolving PALTC setting. AMDA offers opportunities to learn about best practices and activities that can maximize the quality of care and quality of life for patients.
