37 distributional impacts of climate policy in the design and implementation of every policy (Agyeman 2013;
38 Castán Broto and Westman 2017); align mitigation with other objectives such as inclusion and poverty
39 reduction (Hughes and Hoffmann 2020; Rice et al. 2020; Hess and McKane 2021); represent a variety of
40 voices, especially those of the most vulnerable (Bullard et al. 2008; Temper et al. 2018); and rely on open
41 processes of participation (Anguelovski et al. 2016; Bouzarovski et al. 2018; Rice et al. 2020) (*robust*
42 *evidence, high agreement*).

43 Distributive approaches to climate justice address injustices related to access to resources and protection
44 from impacts. There is an important difference between affirmative and transformative justice action
45 (Agyeman et al. 2016; Castán Broto and Westman 2019; Fraser 1995): Affirmative action includes policies
46 and strategies that seek to correct inequitable outcomes without disturbing the underlying political

1 framework while transformative action seeks to correct inequitable outcomes by restructuring the underlying
2 framework that produces inequalities.

3 Transformative action that responds to distributive justice concerns include economy wide actions via
4 stimulus packages (such as the European Green Deal and the New Green Deal in the US (see Section 13.9.5)).
5 Other examples are the increasing number of climate litigation suits that are transforming the way distributive
6 dimensions of climate justice are understood (Section 13.4.2).

7

8 **13.9.4 Net zero emissions targets**

9 The last few years have seen a proliferation of net zero emission targets set by national and regional
10 governments, cities as well as companies and institutions (NewClimate Institute and Data Driven EnviroLab
11 2020; Black et al. 2021; Rogelj et al. 2021) (see also Cross-Chapter Box 3 in Chapter 3). Meeting these
12 targets implies economy wide systemic change (*medium evidence, high agreement*).

13 The Energy & Climate Intelligence Unit (ECIU) Net Zero Tracker divides countries in to those which have
14 net zero emissions achieved, have it in law, have proposed legislation, have it in policy documents or have
15 emission reduction targets under discussion in some form. A recent study estimated that 131 countries have
16 either adopted, announced or are discussing net zero GHG emissions targets, covering 72% of global
17 emissions (Höhne et al. 2021). Out of those, as of 1st October 2021, the ECIU Net Zero Tracker states that
18 Germany, Sweden, the European Union, Japan, United Kingdom, France, Canada, South Korea, Spain,
19 Denmark, New Zealand, Hungary and Luxembourg have net zero targets set in law (ECIU 2021).

20 Some have argued that the expansion of these emission reduction targets marks an important increase in
21 climate mitigation momentum since the Paris Agreement of 2015 and the 2018 IPCC Special Report on
22 Global Warming of 1.5°C (Black et al. 2021; Höhne et al. 2021). On the other hand net zero emission targets
23 in their current state vary enormously in scope, quality and transparency – with many countries at the
24 discussion stage - and this makes scrutiny and comparison difficult (NewClimate Institute and Data Driven
25 EnviroLab 2020; Black et al. 2021; Rogelj et al. 2021).

26 In order to realise the mitigation potential of net zero emission targets some areas within the targets might
27 need to be changed. For example, this includes clearer definitions; well defined timeframes and scopes;
28 focusing on direct emission reductions within their own territory; minimal reliance on offsets; scrutiny of
29 use and risks of CO₂ removal; attention to equity, near-term action coupled with long-term intent setting;
30 and ongoing monitoring and review (Levin et al. 2020; NewClimate Institute and Data Driven EnviroLab
31 2020; Black et al. 2021; Höhne et al. 2021; Rogelj et al. 2021; World Bank 2021b) (*medium evidence, high
32 agreement*).

33

34 **13.9.5 Systemic responses for climate mitigation**

35 There is now a significant body of work which explicitly states, or implicitly accepts, that systemic change
36 may be necessary to deliver successful climate mitigation, including net zero targets. Newell phrases this as
37 the difference between ‘plug and play’ mitigation applications where one aspect of a system is changed while
38 everything in the system remains the same compared to systemic change, with change affecting all the system
39 (Newell 2021a,b). This section highlights an emergent, multi-disciplinary literature since IPCC AR5, which
40 suggests that acceleration to decarbonised systems via a sustainable development pathway may be better
41 achieved by moving from a single policy instrument or mix of policies approach to a systemic economy wide
42 approach (see Figure 13.6).

43 The complexity and multi-faceted challenges of rapidly decarbonising our current interconnected systems
44 (such as energy, food, health) in a just way has led Michaelowa et al. (2018) to conclude that implementation
45 of strong mitigation policy packages that are needed requires a systemic change in policymaking.

1 Multiple modelling assessments of different development and mitigation pathways are available. Most of
2 these analyses which lead to significant climate mitigation assume significant systemic change across social,
3 technological, and economic aspects of a country (for example, India (Gupta et al. 2020); Japan (Sugiyama
4 et al. 2021)) and the globe (Rogelj et al. 2015; Dejuán et al. 2020).

5 UNEP (2020) argued that major, long term sectoral transformation across multiple systems is needed to reach
6 net zero GHG emissions. Bernstein and Hoffmann (2019) and Rockström et al. (2017) argue that the presence
7 of multi-level, multi-sectoral lock-ins of overlapping and interdependent political, economic, technological
8 and cultural forces mean that a new approach of co-ordinated, cross-economy, systemic climate mitigation
9 is necessary. Creutzig et al. (2018) propose a resetting of the approach to consumption and use of resources
10 to that of demand side solutions, which would have ongoing economy-wide systemic implications.

11 Others focus more on single system reconfigurations, such as the energy system (Matthes 2017; Tozer 2020);
12 urban systems (Holtz et al. 2018); or the political system (Somerville 2020; Newell and Simms 2020).
13 Becken (2019) argues that only systemic changes at a large scale will be sufficient to break or disrupt existing
14 arrangements and routines in the tourism industry

15 Others argue for thinking about mitigation in even wider ways. O'Brien (2018) posits that sector-focused, or
16 a silo approach, to mitigation may need to give way to decisions and policies which reach across sectoral,
17 geographic and political boundaries and involve a broad set of interrelated processes – practical, political
18 and personal. Gillard et al. (Gillard et al. 2016) argue that a response to climate change has to move beyond
19 incremental responses, aiming instead for a society wide transformation which goes beyond a system
20 perspective to include learning from social theory; while Eyre et al. (2018) argue that moving beyond
21 incremental emissions reductions will require expanding the focus of efforts beyond the technical to include
22 people, and their behaviour and attitudes. Stoddard et al. (2021) argue that 'more sustainable and just futures
23 require a radical reconfiguration of long-run socio-cultural and political economic norms and institutions'.
24 They focus on nine themes: international climate governance, the vested interests of the fossil fuel industry,
25 geopolitics and militarism, economics and financialisation, mitigation modelling, energy supply systems,
26 inequity, high carbon lifestyles and social imaginaries.

27

28 **13.9.6 Economy-wide measures**

29 Economy wide stimulus packages which have occurred post COVID-19, and in some cases in response to
30 environmental concerns, have the ability to undermine or aid climate mitigation (*medium evidence, high
31 agreement*). Attention in the early efforts of their development and design can contribute to shifting
32 sustainable development pathways and net zero outcomes, whilst meeting short term economic goals
33 (Hepburn et al. 2020; Hanna et al. 2020) (*medium evidence, high agreement*)

34 Economy-wide packages, as a way to stimulate and/or restructure domestic economies to deliver particular,
35 desired outcomes is a widely accepted tool of government (for example the Roosevelt's New Deal packages
36 in the US between 1933 and 1939). A number of country-level stimulus package were put in place after the
37 2008 Global Recession, and there was support for a Global Green New Deal from UNEP (Steiner 2009;
38 Barbier 2010). Cross-economy structural change packages may provide opportunities for another approach
39 to accelerate climate mitigation.

40 This approach has already been taken up to some degree by a number of countries / blocs. For example,
41 California as well as Germany, through the German *Energiewende*, are early examples of a US state and a
42 country which have tried to link their economies to a sustainable future through energy-wide efforts of
43 structural change (Morris and Jungjohann 2016; Burger et al. 2020a).

44 In addition to these economy wide measures, there have since been cross-economy Green New Deals
45 implemented such as the European Green Deal (Elkerbout et al. 2020; Hainsch et al. 2020; UNEP 2020)(see

1 also Box 13.1) with calls for other New Deals (e.g. a Blue New Deal (Dundas et al. 2020)) or deals to bring
2 together climate and justice goals (Hathaway 2020; MacArthur et al. 2020).

3 The COVID-19 Pandemic has resulted in global economic recession, which many Governments have
4 responded to with economic stimulus programs. See also Cross-Chapter Box 1 in Chapter 1 on COVID-19.
5 It has also led to more analysis of the potential of cross-economy stimulus packages to benefit climate goals,
6 including what lessons can be learned from the stimulus packages put in place as a result of the 2008-9
7 Global Recession.

8 The United Nations Environment Programme (UNEP) reviewed the green stimulus plans of the G20
9 following the 2008-9 recession to examine what worked; what did not; and the lessons which could be learnt
10 (Barbier 2010). This work was updated (Barbier 2020) and concluded that the constituents of successful
11 green stimulus frameworks were long term commitments in public spending; pricing reform; ensuring
12 concerns about affordability were overcome; and minimising unwanted distributional impacts. Others argue
13 that post 2008 recession stimulus package outcomes benefited both environmental and industrial objectives
14 and that a long-term policy commitment to the transition to a sustainable, low carbon economy makes sense
15 from both an environmental and industrial strategy point of view (Fankhauser et al. 2013).

16 With the outbreak of the COVID-19 Pandemic in 2020, past stimulus packages have been further
17 investigated. One study interviewed 231 central bank officials and identified 5 key policies for both economic
18 multipliers and climate impacts metrics (Hepburn et al. 2020). These were expenditure on clean physical
19 infrastructure; building energy efficiency retrofits; investment in education and training; natural capital
20 investment; and clean R and D. However, the mix of effective policies may differ in lower and middle income
21 countries: rural support spending was more relevant, while clean R and D was less so. The study illuminated
22 that there were different phases to recovery packages: the initial 'rescue' spending but then a second
23 'recovery' phase that can be more fairly rated green or not green. Recovery phase policies can deliver both
24 economic and climate goals -- co-benefits can be captured (i.e. support for EV infrastructure can also reduce
25 local air pollution etc.) -- but package design is important (Hepburn et al. 2020).

26 Others provide a framework which allows a systematic evaluation of options, given objectives and indicators,
27 for COVID-19 stimulus packages (e.g. (Dupont et al. 2020; Jotzo et al. 2020; OECD 2021c)). Jotzo et al.
28 (2020) conclude that the programmes that most closely match green stimulus are afforestation and ecosystem
29 restoration programmes, energy efficiency upgrades and RE projects. These type of policies provide short
30 term goals of COVID-19 whilst also making progress on longer terms objectives (Jotzo et al. 2020). The
31 IMF concluded that a comprehensive mitigation policy package combining carbon pricing and government
32 green infrastructure spending (that is partly debt financed) can reduce emissions substantially while boosting
33 economic activity, supporting the recovery from the COVID-19 pandemic (Jaumotte et al. 2020).

34 Conversely, other short term fiscal or recovery measures in stimulus packages may perpetuate high carbon
35 and environmental damaging systems. These include fossil fuel based infrastructure investment; fiscal
36 incentives for high carbon technologies or projects; waivers or roll-backs of environmental regulation;
37 bailouts of fossil fuel intensive companies without conditions for low carbon transitions or environmental
38 sustainability (UNEP 2020; O'Callaghan and Murdock 2021; Vivid Economics 2021).

39 Of the USD17.2 trillion so far spent on stimulus packages, USD4.8 trillion (28% of the total as of July 2021)
40 is linked to environmental outcomes (Vivid Economics 2021). This study relates to 30 countries: the G20
41 and 10 others. The packages in EU, Denmark, Canada, France, Spain, the UK, Sweden, Finland and Germany
42 (German Federal Ministry of Finance 2020; Vivid Economics 2021) result in net benefits for the
43 environment. A number of studies provide differing conclusions with respect to net benefits or otherwise for
44 the environment for a number of countries (Climate Action Tracker 2020; UNEP 2020; Vivid Economics
45 2021). An OECD database found that, as of mid-July 2021, 21% of economic recovery spending in OECD,
46 EU and Key Partners is allocated to environmentally positive measures (OECD 2021c). O'Callaghan and
47 Murdock (2021) reviewed the 50 countries with the greatest stimulus spend in 2020 and find that 13% of the

1 spend is directed to long term recovery type measures, of which 18% is spent on green recovery. This is a
2 total of 2.5% of total spend or USD368bn on green initiatives.

3

4 **13.9.7 Steps for acceleration**

5 The multi-disciplinary literature exploring how to accelerate climate mitigation and transition to low GHG
6 economies and systems has grown rapidly over the last few years. Acceleration is also confirmed as an
7 important sub-theme of the more specific transition literature (Köhler et al. 2019). While literature focusing
8 on how to accelerate the impact of climate mitigation is derived from empirical evidence, there is very little
9 *ex post* evidence of directed acceleration approaches.

10 The overlapping discussions of how to accelerate climate mitigation; transition to low carbon economies;
11 and shift development pathways depends heavily on country specific dynamics in political coalitions,
12 material endowments, industry strategy, cultural discourses, and civil society pressures (Sections 13.2, 13.3,
13 13.4, 13.7, and 13.8). Ambition for acceleration at different scales and stringency (whether for cities, country
14 climate policies, country industrial strategies, or national economic restructuring) increase governance
15 challenges, including coordination across stakeholders, institutions, and scales. ‘There is therefore no “one-
16 size-fits-all” blueprint for accelerating low-carbon transitions’ (Geels et al. 2017a; Roberts et al. 2018)
17 (*medium evidence, high agreement*).

18 Markard et al. (2020) describe the key challenges to accelerating climate mitigation and sustainability
19 transitions as:

- 20 1. the ability for low carbon innovations to emerge in whole systems. Two critical issues need to occur
21 to overcome this challenge a) complementary interactions between different elements. For example,
22 in an electricity system, the integration of renewable energy requires complementary storage
23 technologies etc. and b) changes in system architecture. Thus in the accelerating phase, policy has
24 to shift from stimulating singular innovations towards managing wider system transformation.
- 25 2. the need for greater interactions between adjacent systems: interactions between multiple systems
26 increases the complexity of the transition. Policies are linked to institutions or government
27 departments, and they are often compartmentalised into different policy areas (eg energy policy and
28 transport policy). Increasing and coordinating that interaction adds complexity.
- 29 3. the resistance from declining industries; acceleration of sustainability transitions will involve the
30 phase out of unsustainable technologies. As a result acceleration towards a sustainability transition
31 may be resisted – whether business models, or where jobs are involved. Political struggles and
32 conflicts are an inherent part of accelerating transitions, one strategy to deal with this resistance is
33 to accomplish wide societal support for long term transition targets and to form broad constituencies
34 of actors in favour of those transitions.
- 35 4. the need for changes in consumer practices and routines; this challenge relates to changes in social
36 practices that may be required for mainstreaming of sustainable technologies. For example, electric
37 vehicles require changes in trip planning and refuelling practices. Reducing levels or types of
38 consumption is also desirable.
- 39 5. coordination challenges in policy and governance. There is an increasing complexity of governance
40 which can be overcome by stronger vertical and horizontal policy coordination across systems.

41 The acceleration literature links two over-arching actions: first, a strategic targeting approach to overcoming
42 the challenges to acceleration by a parallel focus on undermining high carbon systems whilst simultaneously
43 encouraging low carbon systems; and second, focusing on a coordinated, cross-economy systemic response,
44 including harnessing enabling conditions (Geels et al. 2017b; Rosenbloom and Rinscheid 2020; Hvelplund
45 and Djørup 2017; Gomez Echeverri 2018; Markard 2018; Tvinnereim and Mehling 2018; European
46 Environment Agency 2019; Newell and Simms 2020; Otto et al. 2020; Rogelj et al. 2015; Strauch 2020;

1 O'Brien 2018; Roberts et al. 2018; Hess 2019; Kotilainen et al. 2019; Victor et al. 2019; Burger et al. 2020a;
2 Hsu et al. 2020b; Rosenbloom et al. 2020) (*robust evidence, high agreement*).

3 Strategic targeting, or the identifying of specific intervention points (Kanger et al. 2020), points of leverage
4 (Abson et al. 2017), or upward cascading tipping points (Sharpe and Lenton 2021), broadly means choosing
5 particular actions which will lead to a greater acceleration of climate mitigation across systems. For example,
6 Dorninger et al (2020) provide a quantitative systematic review of empirical research addressing
7 sustainability interventions. They take 'leverage points' – places in complex systems where relatively small
8 changes can lead to potentially transformative systemic changes – to classify different interventions
9 according to their potential for system wide transformative change. They argue that 'deep leverage points' –
10 the goals of a system, its intent, and rules – need to be addressed more directly, and they provide analysis of
11 the food and energy systems.

12 The strategic choosing of policies and points of intervention is linked to the importance of choosing self-
13 reinforcing actions for acceleration (for example, (Rosenbloom et al. 2018; Butler-Sloss et al. 2021; Sharpe
14 and Lenton 2021; Jordan and Moore 2020; Bang 2021). Butler-Sloss et al. (2021) explains the types of self-
15 reinforcing actions (or feedback loops) which can encourage or undermine rapid transformation of energy
16 systems.

17 An example of this first overarching action, the strategic targeting of the challenges to acceleration, is the
18 focus on undermining carbon- intensive systems, thereby reducing opposition to more generalised
19 acceleration policies, including the encouragement of low carbon systems (Rosenbloom 2018; Roberts and
20 Geels 2019; Hvelplund and Djørup 2017; Victor et al. 2019; Rosenbloom et al. 2020; Rosenbloom and
21 Rinscheid 2020) (*robust evidence, high agreement*). Undermining high carbon systems includes deliberately
22 phasing out unsustainable technologies and systems (Kivimaa and Kern 2016; David 2017; Johnsson et al.
23 2019; UNEP 2019b; Carter and McKenzie 2020; European Environment Agency 2019; Newell and Simms
24 2020); confronting the issues of incumbent resistance (Roberts et al. 2018); and avoiding future emissions
25 and energy excess by reducing demand (Rogelj et al. 2015; UNEP 2019b; Victor et al. 2019).

26 Other strategic goals include tackling the equity and justice issues of 'stranded regions' (Spencer et al. 2018);
27 paying greater attention to system architecture to enable increased acceleration to low carbon electricity
28 supply, in this case in the wind industry (McMeekin et al. 2019); and the importance of maintaining global
29 ecosystem of low carbon supply chains (Goldthau and Hughes 2020).

30 Other strategic goals combine national and global action. For example, global NGO coalitions have formed
31 around strategic policy outcomes such as the 'Keep it in the Ground' movement (Carter and McKenzie 2020),
32 and are supported via coordinated networks, such as the Powering Past Coal Alliance (Jewell et al. 2019),
33 and with knowledge dissemination, for example, the 'Fossil Fuel Cuts Database' (Gaulin and Le Billon
34 2020).

35 The second overarching point highlighted by the literature is the benefits of focusing on a coordinated, cross-
36 economy systemic response. Coordination is central to this. For example, coordination of actions and
37 coherent narratives across sectors and cross economy, including within and between all governance levels
38 and scales of actions, is beneficial for acceleration (Zürn and Faude 2013; Hawkey and Webb 2014; Huttunen
39 et al. 2014; Magro et al. 2014; Warren et al. 2016; Köhler et al. 2019; Kotilainen et al. 2019; McMeekin et
40 al. 2019; Victor et al. 2019; Hsu et al. 2020b) (*robust evidence, high agreement*). Victor et al. (2019) provide
41 a framework of how to prioritise the most urgent actions for climate mitigation and they give practical case
42 studies of how to improve coordination to accelerate reconfiguration of systems for economy wide climate
43 mitigation in sectors such as power; cars; shipping; aviation; buildings; cement; and plastics.

44 However, coordination is a necessary but insufficient condition of acceleration. All enabling conditions are
45 required to deliver systemic transformation (Section 13.9.2).

1 Other disciplines argue that social transformation is likely to be as important as the technical challenges in a
2 coordinated, cross-economy approach to acceleration. For example, some argue for social tipping
3 interventions (STI) alongside other technical and political interventions so that they can ‘activate contagious
4 processes of rapidly spreading technologies, behaviours, social norms, and structural reorganisation’ (Otto
5 et al. 2020). They argue that these STIs are *inter alia*: removing fossil fuel subsidies and incentivising
6 decentralised energy generation; building carbon neutral cities; divesting from assets linked to fossil fuels;
7 revealing the moral implications of fossil fuels; strengthening climate education and engagement; and
8 disclosing information of GHG emissions (Otto et al. 2020). Others illuminate the importance of narratives
9 and framings in the take-up (or not) of acceleration actions (Sovacool et al. 2020). Others are optimistic
10 about the possibilities of transformation but also highlight the importance of political economy for rapid and
11 just transitions (Newell and Simms 2020; Newell 2021).

12 In summary, a synthesis of the multi-disciplinary, acceleration literature suggests that climate mitigation is
13 a multifaceted problem which spans cross-economy and society issues, and that solutions to acceleration
14 may lie in coordinated systemic approaches to change and strategic targeting of leverage points. Broadly,
15 this literature agrees on a dual approach of non-incremental systemic change and a targeting of specific
16 acceleration challenges, with tailored actions drawing on enabling conditions. The underlying argument of
17 this is that there is a strategic logic to focusing on actions which undermine high carbon systems at the same
18 time as encouraging low carbon systems. If high carbon systems are weakened then this may reduce the
19 opposition to policies and actions aimed at accelerating climate mitigation, enabling more support for low
20 carbon systems. In addition, targeting of actions which may create ‘tipping point cascades’ which increase
21 the rate of decarbonisation may also be beneficial. Finally, new modes of governance may be better suited
22 to this approach in the context of transformative change.

23

24 **13.10 Further research**

25 Research has expanded in a number of areas relevant to climate mitigation, yet there is considerable scope
26 to add to knowledge. Key areas for research exist in climate institutions and governance, politics, policies
27 and acceleration of action. In each area there is an overarching need for more *ex post* analysis of impact,
28 more cases from the developing world, and understanding how institutions and policies work in combination
29 with each other.

30

31 **13.10.1 Climate institutions, governance and actors**

- 32 • The different approaches to framework legislation, how it can be tailored to country context and
33 evolve over time, how it diffuses across countries, and *ex post* analysis of its impact.
- 34 • Approaches to mainstreaming climate governance across sectors and at different scales, and
35 developing governmental and non-governmental capacity to bring about long-term low-carbon
36 transformations and associated capacity needs.
- 37 • The drivers of subnational climate action, the scope for coordination or leakage with other scales of
38 action, and the effect, in practice on GHG outcomes.
- 39 • Comparative research on how countries develop NDCs, and whether and how that shapes national
40 policy processes.

41

1 13.10.2 Climate politics

- 2 • The full range of approaches that governments and non-governmental actors may take to overcome
3 lock-in to carbon-intensive activities including through addressing material endowments, cultural
4 values, institutional settings and behaviours.
- 5 • The factors that influence emergence of popular movements for and against climate actions, and
6 their direct and indirect impacts.
- 7 • The role of civic organizations in climate governance, including religious organisations, consumer
8 groups, indigenous communities, labour unions, and development aid organizations.
- 9 • The relationship between climate governance approaches and differing political systems, including
10 the role of corruption on climate governance.
- 11 • The impacts of media – traditional and social – on climate mitigation, including the role of
12 disinformation.
- 13 • The role of corporate actors in climate governance across a broad range of industries.
- 14 • Systematic comparative research on the differing role of climate litigation across various juridical
15 systems.

17 13.10.3 Climate policies

- 18 • Greater *ex post* empirical studies of mitigation policy outcomes, their design features, the impacts of
19 policy instruments under different conditions of implementation, especially in developing countries.
20 Such research needs to assess the effectiveness, economic and distributional effects, co-benefits and
21 side effects, and transformational potential of mitigation policies.
- 22 • Understand how packages of policies are designed and implemented, including with attention to
23 local context and trade-offs.
- 24 • Policy design and institutional needs for the explicit purpose of net zero transitions.
- 25 • Greater understanding of the differences between, and benefits of, policy packages and economy
26 wide measures for in-system and cross-system structural change.
- 27 • Policies and packages for emissions sources that are unregulated or under-regulated, including
28 industrial and non-CO₂ emissions.
- 29 • The existence and extent of carbon leakage across countries, the relative impact of different channels
30 of leakage, and the implications of policy instruments designed to address leakage.

32 13.10.4 Coordination and acceleration of climate action

- 33 • How to ensure a just transition that gains wide popular support through research on actual and
34 perceived distributional effects across countries and contexts.
- 35 • How to coordinate and integrate for climate mitigation, between what actors, sectors, governance
36 scale and goals, and how to evaluate.
- 37 • Knowledge on the political and policy related links between adaptation and mitigation across sectors
38 and countries.

- 1 • Further theoretical and empirical research on the necessary institutional, cultural, social and political
2 conditions to accelerate climate mitigation.
- 3 • How to transform developed and developing economies and societies for acceleration, including by
4 shifting development pathways.
5
- 6 • The approaches to, and value of, coordinated, cross economy structural change, including Green
7 New Deal approaches, as a way to accelerate GHG reduction.
8

9

10 **Frequently Asked Questions (FAQs)**

11 **FAQ 13.1 What roles do national play in climate mitigation, and how can they be effective?**

12 Institutions and governance underpin mitigation. Climate laws provide the legal basis for action,
13 organisations through which policies are developed and implemented, and frameworks through which
14 diverse actors interact. Specific organisations, such as expert committees, can inform emission reduction
15 targets, inform the creation of policies and packages, and strengthen accountability. Institutions enable
16 strategic thinking, building consensus among stakeholders and enhanced coordination.

17 Climate governance is constrained and enabled by countries' political systems, material endowments and
18 their ideas, values and belief systems, which leads to a variety of country specific approaches to climate
19 mitigation.

20 Countries follow diverse approaches. Some countries focus on greenhouse gases emissions by adopting
21 comprehensive climate laws and creating dedicated ministries and institutions focused on climate change.
22 Others consider climate change among broader scope of policy objectives, such as poverty alleviation, energy
23 security, economic development and co-benefits of climate actions, with the involvement of existing
24 agencies and ministries. See also FAQ 13.3 on subnational climate mitigation.

25

26 **FAQ 13.2 What policies and strategies can be applied to combat climate change?**

27 Institutions can enable creation of mitigation and sectoral policy instruments; policy packages for low-carbon
28 system transition, and economy wide measures for systemic restructuring. Policy instruments to reduce
29 greenhouses gas emissions include economic instruments, regulatory instruments and other approaches.

30 Economic policy instruments directly influence prices to achieve emission reductions through taxes, permit
31 trading, offset systems, subsidies, and border tax adjustments, and are effective in promoting implementation
32 of low-cost emissions reductions. Regulatory instruments help achieve specific mitigation outcomes
33 particularly in sectoral applications, by establishing technology or performance requirements. Other
34 instruments includes information programs, government provision of goods, services and infrastructure,
35 divestment strategies, and voluntary agreements between governments and private firms.

36 Climate policy instruments can be sector-specific or economy-wide and could be applied at national,
37 regional, or local levels. Policymakers may directly target GHG emission reduction or seek to achieve
38 multiple objectives, such as urbanization or energy security, with the effect of reducing emissions. In
39 practice, climate mitigation policy instruments operate in combination with other policy tools, and require
40 attention to the interaction effects between instruments. At all levels of governance, coverage, stringency
41 and design of climate policies define their efficiency in reducing greenhouse gases emissions.

42 Policy packages, when designed with attention to interactive effects, local governance context, and harnessed
43 to a clear vision for change, are better able to support socio-technical transitions and shifts in development

1 pathways toward low carbon futures than individual policies. See also Chapter 14 on international climate
2 governance.

3

4 **FAQ 13.3 How can actions at the sub-national level contribute to climate mitigation?**

5 Sub-national actors (e.g. individuals, organizations, jurisdictions and networks at regional, local and city
6 levels) often have a remit over areas salient to climate mitigation, such as land use planning, waste
7 management, infrastructure, housing, and community development. Despite constraints on legal authority
8 and dependence on national policy priorities in many countries, subnational climate change policies exist in
9 more than 120 countries. However, they often lack national support, funding, and capacity, and adequate
10 coordination with other scales. Sub-national climate action in support of specific goals is more likely to
11 succeed when linked to local issues such as travel congestion alleviation, air pollution control.

12 The main drivers of climate actions at sub-national levels include high levels of citizen concern, jurisdictional
13 authority and funding, institutional capacity, national level support and effective linkage to development
14 objectives. Subnational governments often initiate and implement policy experiments that could be scaled to
15 other levels of governance.

1 **Executive summary**

2 **International cooperation is having positive and measurable results (*high confidence*).** The Kyoto
3 Protocol led to measurable and substantial avoided emissions, including in 20 countries with Kyoto first
4 commitment period targets that have experienced a decade of declining absolute emissions. It also built
5 national capacity for GHG accounting, catalysed the creation of GHG markets, and increased
6 investments in low-carbon technologies (*medium confidence*). Other international agreements and
7 institutions have led to avoided CO₂ emissions from land-use practices, as well as avoided emissions of
8 some non-CO₂ greenhouse gases (*medium confidence*). {14.3, 14.5, 14.6}

9 **New forms of international cooperation have emerged since AR5 in line with an evolving**
10 **understanding of effective mitigation policies, processes, and institutions. Both new and pre-**
11 **existing forms of co-operation are vital for achieving climate mitigation goals in the context of**
12 **sustainable development (*high confidence*).** While previous IPCC assessments have noted important
13 synergies between the outcomes of climate mitigation and achieving sustainable development
14 objectives, there now appear to be synergies between the two processes themselves (*medium*
15 *confidence*). Since AR5, international cooperation has shifted towards facilitating national level
16 mitigation action through numerous channels. Now including both processes established under the
17 UNFCCC regime and through regional and sectoral agreements and organisations. {14.2, 14.3, 14.5,
18 14.6}

19 **Participation in international agreements and transboundary networks is associated with the**
20 **adoption of climate policies at the national and sub-national levels, as well as by non-state actors**
21 **(*high confidence*).** International cooperation helps countries achieve long-term mitigation targets when
22 it supports development and diffusion of low-carbon technologies, often at the level of individual
23 sectors, which can simultaneously lead to significant benefits in the areas of sustainable development
24 and equity (*medium confidence*). {14.2, 14.3, 14.5, 14.6}

25 **International cooperation under the UN climate regime has taken an important new direction**
26 **with the entry into force of the 2015 Paris Agreement, which strengthened the objective of the UN**
27 **climate regime, including its long-term temperature goal, while adopting a different architecture**
28 **to that of the Kyoto Protocol to achieve it (*high confidence*).** The core national commitments under
29 the Kyoto Protocol have been legally binding quantified emission targets for developed countries tied
30 to well-defined mechanisms for monitoring and enforcement. By contrast, the commitments under the
31 Paris Agreement are primarily procedural, extend to all parties, and are designed to trigger domestic
32 policies and measures, enhance transparency, and stimulate climate investments, particularly in
33 developing countries, and to lead iteratively to rising levels of ambition across all countries (*high*
34 *confidence*). Issues of equity remain of central importance in the UN climate regime, notwithstanding
35 shifts in the operationalisation of ‘common but differentiated responsibilities and respective
36 capabilities’ from Kyoto to Paris (*high confidence*). {14.3}

37 **There are conflicting views on whether the Paris Agreement’s commitments and mechanisms will**
38 **lead to the attainment of its stated goals.** Arguments in support of the Paris Agreement are that the
39 processes it initiates and supports will in multiple ways lead, and indeed have already led, to rising
40 levels of ambition over time. The recent proliferation of national mid-century net-zero GHG targets can
41 be attributed in part to the Paris Agreement (*medium confidence*). Moreover, its processes and
42 commitments will enhance countries’ abilities to achieve their stated level of ambition, particularly
43 among developing countries (*medium confidence*). Arguments against the Paris Agreement are that it
44 lacks a mechanism to review the adequacy of individual Parties’ nationally determined contributions
45 (NDCs), that collectively current NDCs are inconsistent in their level of ambition with achieving the
46 Paris Agreement’s temperature goal, that its processes will not lead to sufficiently rising levels of
47 ambition in the NDCs, and that NDCs will not be achieved because the targets, policies and measures

1 they contain are not legally binding at the international level (*medium confidence*). To some extent,
2 arguments on both sides are aligned with different analytic frameworks, including assumptions about
3 the main barriers to mitigation that international cooperation can help overcome (*medium confidence*).
4 The extent to which countries increase the ambition of their NDCs and ensure they are effectively
5 implemented will depend in part on the successful implementation of the support mechanisms in the
6 Paris Agreement, and in turn will determine whether the goals of the Paris Agreement are met (*high*
7 *confidence*). {14.2, 14.3, 14.4}

8 **International cooperation outside the UNFCCC processes and agreements provides critical**
9 **support for mitigation in particular regions, sectors and industries, for particular types of**
10 **emissions, and at the sub- and trans-national levels (*high confidence*).** Agreements addressing ozone
11 depletion, transboundary air pollution, and release of mercury are all leading to reductions in the
12 emissions of specific greenhouse gases (*high confidence*). Cooperation is occurring at multiple
13 governance levels including cities. Transnational partnerships and alliances involving non-state and
14 sub-national actors are also playing a growing role in stimulating low-carbon technology diffusion and
15 emissions reductions (*medium confidence*). Such transnational efforts include those focused on climate
16 litigation; the impacts of these are unclear but promising. Climate change is being addressed in a
17 growing number of international agreements operating at sectoral levels, as well as within the practices
18 of many multilateral organisations and institutions (*high confidence*). Sub-global and regional
19 cooperation, often described as climate clubs, can play an important role in accelerating mitigation,
20 including the potential for reducing mitigation costs through linking national carbon markets, although
21 actual examples of these remain limited (*high confidence*). {14.2, 14.4, 14.5, 14.6}

22 **International cooperation will need to be strengthened in several key respects in order to support**
23 **mitigation action consistent with limiting temperature rise to well below 2°C in the context of**
24 **sustainable development and equity (*high confidence*).** Many developing countries' NDCs have
25 components or additional actions that are conditional on receiving assistance with respect to finance,
26 technology development and transfer, and capacity building, greater than what has been provided to
27 date (*high confidence*). Sectoral and sub-global cooperation is providing critical support, and yet there
28 is room for further progress. In some cases, notably with respect to aviation and shipping, sectoral
29 agreements have adopted climate mitigation goals that fall far short of what would be required to
30 achieve the temperature goal of the Paris Agreement (*high confidence*). Moreover, there are cases where
31 international cooperation may be hindering mitigation efforts, namely evidence that trade and
32 investment agreements, as well as agreements within the energy sector, impede national mitigation
33 efforts (*medium confidence*). International cooperation is emerging but so far fails to fully address
34 transboundary issues associated with solar radiation modification and carbon dioxide removal (*high*
35 *confidence*) {14.2, 14.3, 14.4, 14.5, 14.6}

36

1 **14.1 Introduction**

2 This chapter assesses the role and effectiveness of international cooperation in mitigating climate
3 change. Such cooperation includes multilateral global cooperative agreements among nation states such
4 as the 1992 United Nations Framework Convention on Climate Change (UNFCCC), and its related
5 legal instruments, the 1997 Kyoto Protocol and the 2015 Paris Agreement, but also plurilateral
6 agreements involving fewer states, as well as those focused on particular economic and policy sectors,
7 such as components of the energy system. Moreover, this chapter assesses the role of transnational
8 agreements and cooperative arrangements between non-state and sub-national actors, including
9 municipal governments, private-sector firms and industry consortia, and civil society organisations.
10 This chapter does not assess international cooperation within the European Union, as this is covered in
11 Chapter 13 of this report.

12 Past IPCC assessment reports have discussed the theoretical literature, providing insights into the
13 rationale for international cooperation, as well as guidance as to its structure and implementation. This
14 chapter limits such theoretical discussion primarily to the new developments since AR5. Important
15 developments in this respect include attention to climate clubs (groups of countries and potentially non-
16 state actors that can work together to achieve particular objectives), and the effects of framing the global
17 climate change mitigation challenge as one of accelerating a socio-technical transition or
18 transformation, shifting development pathways accordingly, in addition to (or rather than) solving a
19 global commons problem. This chapter draws from theory to identify a set of criteria by which to assess
20 the effectiveness of existing forms of international cooperation.

21 The rest of this chapter describes existing cooperative international agreements, institutions, and
22 initiatives with a view to clarifying how they operate, what effects they have, and ultimately, whether
23 they work. At the heart of this international institutional architecture lies the Paris Agreement, which
24 sets the overall approach for international cooperation under the UNFCCC at the global level. In many
25 ways, the Paris Agreement reshapes the structure of such cooperation, from one oriented primarily
26 towards target setting, monitoring, and enforcement, to one that is oriented towards supporting and
27 enabling nationally determined actions (including targets), monitoring as well as catalysing non-state
28 and sub-national actions at multiple levels of governance. In addition to the Paris Agreement, many
29 forms of cooperation have taken shape in parallel: those designed to address other environmental
30 problems that have a significant impact on climate mitigation; those operating at the sub-global or
31 sectoral level; and, those where the main participants are non-state actors. The chapter ends with an
32 overall assessment of the effectiveness of current international cooperation and identifies areas that
33 would benefit from improved and enhanced action.

34

35 **14.1.1 Key findings from AR5**

36 AR5 found that two characteristics of climate change make international cooperation essential: that it
37 is a global commons problem that needs to be addressed in a coordinated fashion at the global
38 scale; and that given the global diversity with respect to opportunities for and cost of mitigation, there
39 are economic efficiencies associated with cooperative solutions (13.2.1.1). Consequently, AR5
40 found evidence to suggest that climate policies that are implemented across geographical regions would
41 be more effective in terms of both their environmental consequences and their economic costs (13.13,
42 13.6, 14.4). AR5 also suggested that regional cooperation could offer opportunities beyond what
43 countries may be able to achieve by themselves. These opportunities are due to geographic proximity,
44 shared infrastructure and policy frameworks, trade, and cross-border investments, and examples
45 included renewable energy pools across borders, networks of energy infrastructure and coordinated
46 forestry policies (1.2, 6.6,15.2, 14.2). AR5 also suggested that policy linkages exist across regional,

1 national, and sub-national scales (13.3.1, 13.5.1.3). For these reasons, AR5 suggested that although the
2 UNFCCC remains the primary international forum for climate negotiations, many other institutions
3 engaged at the global, regional, and local levels do and should play an active role
4 (1.3.3.1,13.4.1.4,13.5). AR5 also noted that the inclusion of climate change issues across a variety of
5 forums often creates institutional linkages between mitigation and adaptation (13.3,13.4.13.5). In
6 addition to centralised cooperation and governance, with a primary focus on the UNFCCC and its
7 associated institutions, AR5 noted the emergence of new transnational climate-related institutions of
8 decentralised authority such as public-private sector partnerships, private sector governance initiatives,
9 transnational NGO programs, and city-led initiatives (13.2,13.3.1,13.12). It noted that these have
10 resulted in a multiplicity of cooperative efforts in the form of multilateral agreements, harmonised
11 national policies and decentralised but coordinated national and regional policies (13.4.1, 13.3.2, 14.4).
12 Finally, it suggested that international cooperation may also have a role in promoting active engagement
13 of the private sector in technological innovation and cooperative efforts leading to technology transfer
14 and the development of new technologies (13.3, 13.9, 13.12).

16 **14.1.2 Developments since AR5**

17 ***14.1.2.1 Negotiation of the Paris Agreement***

18 The key development since AR5 has been the negotiation and adoption of the Paris Agreement, which,
19 building on the UNFCCC, introduces a new approach to global climate governance. This new approach,
20 as discussed below (Section 14.3.1.1), is driven by the need to engage developing countries in emissions
21 reductions beyond those they had taken on voluntarily under the Cancun Agreements, extend mitigation
22 commitments to those developed countries that had rejected or withdrawn from the Kyoto Protocol, and
23 to respond to the rapidly changing geopolitical context (Section 14.3.1.2).

24 ***14.1.2.2 2030 Agenda for Sustainable Development and the Sustainable Development Goals***

25 It has long been clear that a failure to mitigate climate change would exacerbate existing poverty,
26 accentuate vulnerability and worsen inequality (IPCC 2014), but there is an emerging attempt to
27 harmonise mitigation actions with those oriented towards social and economic development. A key
28 development since AR5 is the adoption in 2015 of the 2030 Agenda for Sustainable Development,
29 which contains 17 Sustainable Development Goals (SDGs). This Agenda offers an aspirational
30 narrative, coherent framework and actionable agenda for addressing diverse issues of development
31 through goals that balance the economic, social and environmental dimensions of sustainable
32 development as well as issues of governance and institutions (ICSU ISSC 2015). Scholars have noted
33 that these dimensions of sustainable development are inter-dependent (Nilsson et al. 2016), and, as such
34 it is difficult if not impossible to achieve economic and social gains while neglecting environmental
35 concerns, including climate change (Le Blanc 2015). The SDGs are closely linked to the Paris
36 Agreement, adopted a few weeks later. There is a growing body of literature that examines the
37 interlinkages between SDGs, including SDG 13 (taking urgent action to combat climate change) and
38 others, concluding that without a proper response to climate change, success in many of the other SDGs
39 would be difficult if not impossible (Weitz et al. 2018; ICSU ISSC 2015; Le Blanc 2015; Nilsson et al.
40 2016). Likewise, failure to achieve the SDGs will have a detrimental effect on the ability to limit climate
41 change to manageable levels. Initiatives such as The World in 2050 (TWI2050 2018), a large research
42 initiative by a global consortium of research and policy institutions, work on the premise that pursuing
43 climate action and sustainable development in an integrated and coherent way, based on a sound
44 understanding of development pathways and dynamics, is the strongest approach to enable countries to
45 achieve their objectives in both agreements.

46 ***14.1.2.3 IPCC Special Reports***

47 Further key developments since AR5 include the release of three IPCC special reports. The first of these
48 assessed the differential impacts of limiting climate change to 1.5°C global average warming compared

1 to 2°C warming, indicated the emissions reductions necessary and enabling conditions to stay within
2 this limit (IPCC 2018a). While the events that have unfolded since the report are not yet
3 comprehensively documented in literature, arguably the report has led to a renewed perception of the
4 urgency of climate mitigation (Wolf et al. 2019). In particular, the report appears to have crystallised
5 media coverage in some parts of the world around a need to reduce emissions to net zero by 2050
6 (whether of GHGs or CO₂), rather than delaying such reductions until the latter half of the century, as
7 had been previously understood and indicated in the Paris Agreement. Its release is hence one factor
8 explaining the rise in transnational climate mobilisation efforts (Boykoff and Pearman 2019). It has also
9 played a role, in addition to the Paris Agreement (Geden 2016a), in the numerous announcements,
10 pledges and indications by governments, including by all G-7 countries, of their adoption of net zero
11 GHG targets for 2050. The other two special reports focused on ocean and the cryosphere (IPCC 2019),
12 and the potential of land-related responses to contribute to adaptation and mitigation (IPCC 2020).
13 There has been no literature directly tying the publication of these latter two reports to changes in
14 international cooperation. However, the 25th UNFCCC Conference of Parties in Madrid in 2019
15 convened a dialogue on ocean and climate change to consider how to strengthen mitigation and
16 adaptation action in this context (UNFCCC 2019a, para 31).

19 **14.2 Evaluating international cooperation**

20 This section describes recent insights from social-science theory that can shed light on the need for and
21 ideal structure of international cooperation. This section starts by describing developments in framing
22 the underlying problem, move towards a body of theory describing the benefits of multilateral sub-
23 global action, and ends with a theory-based articulation of criteria to assess the effectiveness of
24 international cooperation.

25 **14.2.1 Framing concepts for assessment of the Paris Agreement**

26 Previous IPCC reports have framed international climate cooperation, and indeed climate mitigation
27 more generally, primarily as addressing a global commons problem (Stavins et al. 2014). In this report,
28 by contrast, multiple framings are considered. Chapter 1 introduces four analytic frameworks:
29 aggregated economic approaches such as cost-benefit analysis, which maps onto the global commons
30 framing; ethical approaches; analysis of transitions and transformations; and psychology and politics of
31 changing course. Here, we highlight some of the findings that are of relevance to international
32 cooperation.

33 When applied to the international context, the public good (or global commons) framing stresses that
34 the incentives for mitigation at the global level are greater than they are for any single country, since
35 the latter does not enjoy the benefits of its own mitigation efforts that accrue outside its own borders
36 (Patt 2017; Stavins et al. 2014). This framing does not preclude countries engaging in mitigation, even
37 ambitious mitigation, but it suggests that these countries' level of ambition and speed of abatement
38 would be greater if they were part of a cooperative agreement.

39 Theoretical economists have shown that reaching such a global agreement is difficult, due to countries'
40 incentives to freeride, namely benefit from other countries' abatement efforts while failing to abate
41 themselves (Barrett 1994; Gollier and Tirole 2015). Numerical models that integrate game theoretic
42 concepts, whether based on optimal control theory or on dynamic programming, consistently confirm
43 this insight, at least in the absence of transfers (Germain et al. 2003; Lessmann et al. 2015; Chander
44 2017). Recent contributions suggest that regional or sectoral agreements, or agreements focused on a
45 particular subset of GHGs, can be seen as building blocks towards a global approach (Asheim et al.

1 2006; Froyn and Hovi 2008; Sabel and Victor 2017; Stewart et al. 2017). In a dynamic context, this
2 gradual approach through building blocks can alleviate the free-riding problem and ultimately lead to
3 global cooperation (Caparrós and Péreau 2017). Much of this literature is subsumed under the concept
4 of “climate clubs,” described in the next section. Other developments based on dynamic game theory
5 suggest that the free-riding problem can be mitigated if the treaties do not prescribe countries’ levels of
6 green investment and the duration of the agreement, as countries can credibly threaten potential free-
7 riders with a short-term agreement where green investments will be insufficient due to the hold-up
8 problem (Battaglini and Harstad 2016). Finally, thresholds and potential climate catastrophes have also
9 been shown, theoretically and numerically, to reduce free-riding incentives, especially for countries that
10 may become pivotal in failing to avoid the threshold (Barrett 2013; Emmerling et al. 2020).

11 In addition to mitigation in the form of emissions abatement, innovation in green technologies also has
12 public good features, leading for the same reasons to less innovation than would be globally ideal (Jaffe
13 et al. 2005). Here as well, theory suggests that there are benefits from cooperation on technology
14 development at the regional or sectoral levels, but also that cooperation on technology, especially for
15 breakthrough technologies, may prove to be easier than for abatement (El-Sayed and Rubio 2014; Rubio
16 2017). In a dynamic context, the combination of infrastructure lock-in, network effects with high
17 switching cost, and dynamic market failures suggests that deployment and adoption of clean
18 technologies is path dependent (Acemoglu et al. 2012; Aghion et al. 2014), with a multiplicity of
19 possible equilibria. This implies that no outcome is guaranteed, although the most likely pathway will
20 depend on economic expectations and initial conditions of the innovation process (Krugman 1991).
21 Therefore, the government has a role to play, either by shifting expectations (e.g. credibly committing
22 to climate policy), or by changing initial conditions (e.g. investing in green infrastructure or subsidising
23 clean energy research) (Acemoglu et al. 2012; Aghion et al. 2014). This result is exacerbated by the
24 irreversibility of energy investments and the extremely long periods of operation of the typical energy
25 investment (Caparrós et al. 2015; Baldwin et al. 2020).

26 While the public goods and global commons framing concentrates on free-riding incentives as the
27 primary barrier to mitigation taking place at a pace that would be globally optimal, other factors arise
28 across the four analytic frameworks. For example, within the political framework, Beiser-McGrath and
29 Bernauer (2021) highlight that not just the incentive to free-ride, but also the knowledge that another
30 major emitter is free-riding, could lessen a country’s political incentive to mitigate. Aklin and
31 Mildemberger (2020) present evidence to suggest that distributive conflict within countries, rather than
32 free riding across countries, is the primary barrier to ambitious national level action. Another barrier
33 could be a lack of understanding and experience with particular policy approaches; there is evidence
34 that participation in cooperative agreements could facilitate information exchange across borders and
35 lead to enhanced mitigation policy adoption (Rashidi and Patt 2018).

36 The analytic approach focusing on transitions and transformation focuses on path dependent processes
37 as an impediment to the shift to low-carbon technologies and systems. Cross-chapter box 12 on
38 Transition Dynamics (Chapter 16) summarizes the key points of this literature. This chapter describes
39 how the two framings focus on different indicators of progress, and potentially different types of
40 cooperative action within the international context. This chapter highlights in later sections conflicting
41 views on whether the Paris Agreement is likely to prove effective (section 14.3.3.2). To some extent,
42 the dichotomy of views aligns with the two framings: analysis implicitly aligned with the global
43 commons framing is negative about the Paris architecture, whereas that aligned with the transitions
44 framing is more positive (Kern and Rogge 2016; Roberts et al. 2018; Patt 2017).

45 Within the global commons framing, the primary indicator of progress is the actual level of GHG
46 emissions, and the effectiveness of policies can be measured in terms of whether such emissions rise or
47 fall (Patt 2017; Hanna and Victor 2021). The fact that the sum of all countries’ emissions has continued
48 to grow (IPCC 2018a), even as there has been a global recognition that they should decline, is seen as

1 being consistent with the absence of a strong global agreement. Within this framing, there is
2 traditionally an emphasis on treaties' containing self-enforcing agreements (Olmstead and Stavins
3 2012), ideally through binding commitments, as a way of dealing with the overarching problem of free-
4 ridership (Barrett 1994; Finus and Caparrós 2015; Tulkens 2019). However, as discussed above, the
5 emphasis has now shifted to a gradual cooperation approach, either regional or sectoral, as an alternative
6 way of dealing with free-riding incentives (Caparrós and Péreau 2017; Sabel and Victor 2017; Stewart
7 et al. 2017). The gradual linkage of emission trading systems (discussed in Section 14.4.4), goes in the
8 same direction. There is also literature suggesting that the diversity of the countries involved may in
9 fact be an asset to reduce the free-rider incentive (Pavlova and De Zeeuw 2013; Finus and McGinty
10 2019), which argues in favour of a system where all countries, irrespectively of their income levels, are
11 fully involved in mitigation, unlike the Kyoto Protocol and in line with the Paris Agreement. Finally,
12 recent efforts have discussed potential synergies between mitigation and adaptation efforts in a strategic
13 context (Bayramoglu et al. 2018) (see Section 14.5.1.2) In general, current efforts go beyond
14 considering climate policy as a mitigation-only issue, much in line with the discussion about linkages
15 between climate change and sustainable development policies described in detail in Chapters 1 and 4
16 of this report.

17 In the transitions framing, by contrast, global emissions levels are viewed as the end (and often greatly
18 delayed) result of a large number of transformative processes. International cooperation may be
19 effective at stimulating such processes, even if a change in global emissions is not yet evident, implying
20 that short-term changes in emissions levels may be a misleading indicator of progress towards long-
21 term goals (Patt 2017). Hanna and Victor (2021) suggest a particular focus on technical advances and
22 deployment patterns in niche low carbon technologies, such as wind and solar power, and electric
23 vehicles. However, this is one among many suggestions: the literature does not identify a single clear
24 indicator to use, and there are many metrics of technological progress and transformation, described in
25 Chapter 16, Section 16.3.3 of this report. These can include national level emissions among countries
26 participating in particular forms of cooperation, as well as leading indicators of such emissions such as
27 changes in low-carbon technology deployment and cost.

28 Just as the transition framing highlights indicators of progress other than global emissions, it de-
29 emphasises the importance of achieving cost-effectiveness with respect to global emissions. Hence, this
30 strand of the literature does not generally support the use of international carbon markets, suggesting
31 that these can delay transformative processes within countries that are key drivers of technological
32 change (Cullenward and Victor 2020). For similar reasons, achieving cross-sectoral cost-effectiveness,
33 a goal of many carbon markets, is not seen as a high priority. Instead, within the transitions framing the
34 emphasis with respect to treaty design is often on providing mechanisms to support parties' voluntary
35 actions, such as with financial and capacity-building support for new technologies and technology
36 regimes (Geels et al. 2019). The transitions literature also highlights impediments to transformation as
37 being sector specific, and hence the importance of international cooperation addressing sector-specific
38 issues (Geels et al. 2019). While such attention often starts with promoting innovation and diffusion of
39 low-carbon technologies that are critical to a sector's functioning, it often ends with policies aimed at
40 phasing out the high-carbon technologies once they are no longer needed (Markard 2018). In line with
41 this, many scholars have suggested value in supply-side international agreements, aimed at phasing out
42 the production and use of fossil fuels (Collier and Venables 2014; Piggot et al. 2018; Asheim et al.
43 2019; Newell and Simms 2020).

44 Analytic approaches centred on equity and development figure prominently within this report, with
45 many of the key concepts addressed in Chapter 4. Primarily the focus is on aligning climate policy at
46 the international level with efforts to shift development pathways towards improved quality of life and
47 greater sustainability (see cross chapter box 5 on shifting sustainable development pathways, Chapter
48 4). There are also overlaps between the equity framework and the others. Within the global commons

1 framing, the emphasis is on international carbon markets to reduce the costs from climate policies, and
 2 as way of generating financial flows to developing countries (Michaelowa et al. 2019a). The transitions
 3 framing, while focused empirically primarily on industrialized countries, nevertheless aligns with an
 4 understanding of climate mitigation taking place within a wider development agenda; in many cases it
 5 is a lack of development that creates a barrier to rapid system transformation, which international
 6 cooperation can address (Delina and Sovacool 2018)(see also Cross-chapter Box 12).

8 **14.2.2 Climate clubs and building blocks**

9 A recent development in the literature on international climate governance has been increased attention
 10 to the potential for climate clubs (Victor 2011). Hovi et al. (2016) define these “as any international
 11 actor group that (1) starts with fewer members than the UNFCCC has and (2) aims to cooperate on one
 12 or more climate change-related activities, notably mitigation, adaptation, climate engineering or climate
 13 compensation.” While providing public goods (such as mitigation), they also offer member-only
 14 benefits (such as preferential tariff rates) to entice membership. In practice, climate clubs are sub-global
 15 arrangements, and formal agreement by interstate treaty is not a prerequisite. Actors do not have to be
 16 states, although in the literature on climate clubs states have hitherto dominated. The literature has an
 17 essentially static dimension that focuses on the incentives for actors to join such a club, and a dynamic
 18 one, which focuses on the “building blocks” for global cooperative agreements.

19 The literature focusing on the static aspects of clubs highlight that they represent “coalitions of the
 20 willing” (Falkner 2016a; Gampfer 2016; Falkner et al. 2021), which offer a package of benefits, part of
 21 which are pure public goods (available also to non-club members), and others are club benefits that are
 22 only available to members (Hovi et al. 2016). The members-only or excludable part can be a system of
 23 transfers within the club to compensate the countries with higher costs. For example, the benefit from
 24 participating in the club can be to have access to a common emissions trading system, which in general
 25 is more attractive the larger the diversity of the countries involved, although this is not a general result
 26 as discussed in detail in Doda and Taschini (2017). However, as costs and effort sharing agreements
 27 are unsuccessful in a static context (Barrett 1994), mainly due to free-rider incentives, several studies
 28 have proposed using tariffs on trade or other forms of sanctions to reduce incentives for free-riding
 29 (Helm and Sprinz 2000; Eyland and Zaccour 2012; Anouliès 2015; Nordhaus 2015; Al Khourdajie and
 30 Finus 2020). For example, Nordhaus (2015) uses a coalition formation game model to show that a
 31 uniform percentage tariff on the imports of nonparticipants into the club region (at a relatively low tariff
 32 rate of about 2%) can induce high participation within a range of carbon price values. More recently,
 33 Al Khourdajie and Finus (2020) show that border carbon adjustments and an open membership policy
 34 can lead to a large stable climate agreement, including full participation. Table 14.1 presents a number
 35 of key results related to climate clubs from a static context.

36
 37 **Table 14.1 Key climate club static modelling results**

	Aakre et al. (2018)	(Nordhaus 2015)	(Hovi et al. 2017; Sprinz et al. 2018)	(Sælen et al. 2020; Sælen 2020)
Scope	Transboundary black carbon and methane in the Arctic	Global emissions	Global emissions	Global emissions
Modelling method	TM5-FASST model (“reduced-form air quality and impact evaluation tool”)	C-DICE (coalition formation game based on a static version of the multiregional	Agent-based model	Agent-based model

		DICE-RICE optimisation model)		
Border tax adjustment	No	Yes	No	No
Key results	Black carbon can be more easily controlled than methane, based on self-interest; inclusion of non-Arctic Council major polluters desirable to control pollutants	For non-participants in mitigation efforts, modest tariffs on trade are advised to stabilize coalition formation for emission reductions	Climate clubs can substantially reduce GHG emissions, provided club goods are present. The (potential) departure of a single major actor (e.g., USA) reduces emissions coverage, yet is rarely fatal to the existence of the club	The architecture of the Paris Agreement will achieve the 2°C goal only under a very fortunate constellation of parameters. Potential (e.g., US) withdrawal further reduces these chances considerably

1

2 In a dynamic context, the literature on climate clubs highlights the co-called ‘building blocks’ approach
3 (Stewart et al. 2013a,b, 2017). This is a bottom-up strategy designed to create an array of smaller-scale,
4 specialised initiatives for transnational cooperation in particular sectors and/or geographic areas with a
5 wide range of participants. As part of this literature, Potoski and Prakash (2013) provide a conceptual
6 overview of voluntary environmental clubs, showing that many climate clubs do not require demanding
7 obligations for membership and that a substantial segment thereof are mostly informational (Weischer
8 et al. 2012; Andresen 2014). Also crafted onto the building blocks approach, Potoski (2017)
9 demonstrates the theoretical potential for green certification and green technology clubs. Green (2017)
10 further highlights the potential of “pseudo-clubs” with fluid membership and limited member benefits
11 to promote the diffusion and uptake of mitigation standards. Falkner et al. (2021) suggest a typology of
12 normative, bargaining, and transformational clubs. Before the adoption of the Paris Agreement, some
13 literature suggested that the emergence of climate clubs in parallel to the multilateral climate regime
14 would lead to “forum shopping”, with states choosing the governance arrangement that best suits their
15 interests (McGee and Taplin 2006; van Asselt 2007; Biermann et al. 2009; Oh and Matsuoka 2017).
16 However, more recent literature suggests that climate clubs complement rather than challenge the
17 international regime established by the UNFCCC (van Asselt and Zelli 2014; Draguljić 2019; Falkner
18 2016a).

19 In this dynamic context, one question is whether to negotiate a single global agreement or to start with
20 smaller agreements in the hope that they will eventually evolve into a larger agreement. It has been
21 debated extensively in the context of free trade whether a multilateral (global) negotiating approach is
22 preferable to a regional approach, seen as a building block towards global free trade. Aghion et al.
23 (2007) analysed this issue formally for trade, showing that a leader would always choose to move
24 directly to a global agreement. In the case of climate change, it appears that even the mildest form of
25 club discussed above (an efforts and costs sharing agreement, as in the case of the linkage of emissions
26 trading systems) can yield global cooperation following a building-blocks approach, and that the
27 sequential path relying on building-blocks may be the only way to reach global cooperation over time
28 (Caparrós and Péreau 2017). While the existence of a nearly universal agreement such as the Paris

1 Agreement may arguably have rendered this discussion less relevant, the Paris Agreement co-exists,
2 and will likely continue to do so, with a multitude of sectoral and regional agreements, meaning that
3 this discussion is still relevant for the evolution of these complementary regimes.

4 Results based on an agent-based model suggest that climate clubs results in major emission reductions
5 if there is a sufficiently high provision of the club good and if initial membership by several states with
6 sufficient emissions weight materializes. Such configurations allow the club to grow over time to enable
7 effective global action (Hovi et al. 2017). The departure of a major emitter (specifically the United
8 States) triggered a scientific discussion on the stability of the Paris Agreement. Sprinz et al. (2018)
9 explore whether climate clubs are stable against a leader willing to change its status, e.g., from leader
10 to follower or even completely leaving the climate club, finding in most cases such stability to exist.
11 Related studies on the macroeconomic incentives for climate clubs by Paroussos et al. (2019) show that
12 climate clubs are reasonably stable, both internally and externally (i.e., no member willing to leave and
13 no new member willing to join), and climate clubs that include obligations in line with the 2°C goal
14 combined with financial incentives can facilitate technology diffusion. The authors also show that
15 preferential trade arrangements for low-carbon goods can reduce the macroeconomic effects of
16 mitigation policies. Aakre et al. (2018) show numerically that small groups of countries can limit black
17 carbon in the Arctic, driven mainly for reasons of self-interest, yet reducing methane requires larger
18 coalitions due to its larger geographical dispersal and require stronger cooperation.

19 20 **14.2.3 Assessment criteria**

21 This section identifies a set of criteria for assessing the effectiveness of international cooperation, which
22 is applied later in the chapter. Lessons from the implementation of other multilateral environmental
23 agreements (MEAs) can provide some guidance. There is considerable literature on this topic, most of
24 which predates AR5, and which will therefore not be covered in detail. Issues include ways to enhance
25 compliance, and the fact that a low level of compliance with an MEA does not necessarily mean that
26 the MEA has no effect (Downs et al. 1996; Victor et al. 1998; Weiss and Jacobson 1998). Recent
27 research examines effectiveness from the viewpoint of the extent to which an MEA influences domestic
28 action, including the adoption of implementing legislation and policies (Brandt et al. 2019).

29 Many have pointed to the Montreal Protocol, addressing stratospheric ozone loss, as an example of a
30 successful treaty because of its ultimate environmental effectiveness, and relevance for solving climate
31 change. Scholarship emerging since AR5 emphasises that the Paris Agreement has a greater ‘bottom-
32 up’ character than many other MEAs, including the Montreal or Kyoto Protocols, allowing for more
33 decentralised ‘polycentric’ forms of governance that engage diverse actors at the regional, national and
34 sub-national levels (Ostrom 2010; Jordan et al. 2015; Falkner 2016b; Victor 2016). Given the
35 differences in architecture, lessons drawn from studies of MEA regimes need to be supplemented with
36 assessments of the effectiveness of cooperative efforts at other governance levels and in other forums.
37 Emerging research in this area proposes methodologies for this task (Hsu et al. 2019a). Findings
38 highlight the persistence of similar imbalances between developed and developing countries as at the
39 global level, as well as the need for more effective ways to incentivise private sector engagement in
40 transnational climate governance (Chan et al. 2018).

41 While environmental outcomes and economic performance have been long-standing criteria for
42 assessment of effectiveness, the other elements deserve some note. It is the case that the achievement
43 of climate objectives, such as limiting global average warming to 1.5 – 2°C, will require the transition
44 from high- to low-carbon technologies, and the transformation of the sectors and social environments
45 within which those technologies operate. Such transformations are not linear processes, and hence many
46 of the early steps taken – such as supporting early diffusion of new renewable energy technologies –
47 will have little immediate effect on GHG emissions (Patt 2015; Geels et al. 2017). Hence, activities that

1 contribute to transformative potential include technology transfer and financial support for low-carbon
 2 infrastructure, especially where the latter is not tied to immediate emissions reductions. Assessing the
 3 transformative potential of international cooperation takes these factors into account. Equity and
 4 distributive outcomes are of central importance to the climate change debate, and hence for evaluating
 5 the effects of policies. Equity encompasses the notion of distributive justice which refers to the
 6 distribution of goods, burdens, costs and benefits, as well as procedural-related issues (Kverndokk
 7 2018).

8 Finally, the literature on the performance of other MEAs highlights the importance of institutional
 9 strength, which can include regulative quality, mechanisms to enhance transparency and accountability,
 10 and administrative capacity. Regulative quality includes guidance and signalling (Oberthür et al. 2017),
 11 as well as clear rules and standards to facilitate collective action (Oberthür and Bodle 2016). The
 12 literature is clear that legally binding obligations (which require the formal expression of state consent)
 13 and non-binding recommendations can each be appropriate, depending on the particular circumstances
 14 (Skjærseth et al. 2006), and indeed it has been argued that for climate change non-binding
 15 recommendations may better fit the capacity of global governance organisations (Victor 2011).
 16 Mechanisms to enhance transparency and accountability are essential to collect, protect, and analyse
 17 relevant data about parties' implementation of their obligations, and to identify and address challenges
 18 in implementation (Kramarz and Park 2016; Kinley et al. 2020). Administrative capacity refers to the
 19 strength of the formal bodies established to serve the parties to the regime and help ensure compliance
 20 and goal attainment (Anderl and Behrle 2009; Bauer et al. 2017).

21 In addition to building on the social science theory just described, we recognise that it is also important
 22 to strike a balance between applying the same standards developed and applied to international
 23 cooperation in AR5, and maintaining consistency with other chapters of this report (primarily Chapters
 24 1, 4, 13, and 15). Table 14.2 presents a set of criteria that do this, and which are then applied later in
 25 the chapter.

26
 27 **Table 14.2 Criteria for assessing effectiveness of international cooperation**

Criterion	Description
Environmental outcomes	To what extent does international cooperation lead to identifiable environmental benefits, namely the reduction of economy-wide and sectoral emissions of greenhouse gases from pre-existing levels or 'business as usual' scenarios?
Transformative potential	To what extent does international cooperation contribute to the enabling conditions for transitioning to a zero-carbon economy and sustainable development pathways at the global, national, or sectoral levels?
Distributive outcomes	To what extent does international cooperation lead to greater equity with respect to the costs, benefits, and burdens of mitigation actions, taking into account current and historical contributions and circumstances?
Economic performance	To what extent does international cooperation promote the achievement of economically efficient and cost-effective mitigation activities?
Institutional strength	To what extent does international cooperation create the institutional framework needed for the achievement of internationally agreed-upon goals, and contribute to national, sub-national, and sectoral institutions needed for decentralised and bottom-up mitigation governance?

28

1 **14.3 The UNFCCC and the Paris Agreement**

2 **14.3.1 The UN climate change regime**

3 *14.3.1.1 Instruments & Milestones*

4 The international climate change regime, in evolution for three decades, comprises the 1992 UNFCCC,
5 the 1997 Kyoto Protocol, and the 2015 Paris Agreement. The UNFCCC is a ‘framework’ convention,
6 capturing broad convergence among states on an objective, a set of principles, and general obligations
7 relating to mitigation, adaptation, reporting and support. The UNFCCC categorises parties into Annex
8 I and Annex II. Annex I parties, comprising developed country parties, have a goal to return,
9 individually or jointly, their GHG emissions to 1990 levels by 2000. Annex II parties, comprising
10 developed country parties except for those with economies in transition, have additional obligations
11 relating to the provision of financial and technology support. All parties, including developing country
12 parties, characterised as non-Annex-I parties, have reporting obligations, as well as obligations to take
13 policies and measures on mitigation and adaptation. The UNFCCC also establishes the institutional
14 building blocks for global climate governance. Both the 1997 Kyoto Protocol and the 2015 Paris
15 Agreement are distinct but ‘related legal instruments’ in that only parties to the UNFCCC can be parties
16 to these later instruments.

17 The Kyoto Protocol specifies GHG emissions reduction targets for the 2008-2012 commitment period
18 for countries listed in its Annex B (which broadly corresponds to Annex I to the UNFCCC) (UNFCCC
19 1997, Art. 3 and Annex B). The Kyoto Protocol entered into force in 2005. Shortly thereafter, states
20 began negotiating a second commitment period under the Protocol for Annex B parties, as well as
21 initiated a process under the UNFCCC to consider long-term cooperation among all parties.

22 At COP 13 in Bali in 2007, parties adopted the *Bali Action Plan* that launched negotiations aimed at an
23 agreed outcome enhancing the UNFCCC’s ‘full, effective and sustained implementation’. The agreed
24 outcome was to be adopted at COP 15 in Copenhagen in 2009, but negotiations failed to deliver a
25 consensus document. The result instead was the *Copenhagen Accord*, which was taken note of by the
26 COP. While it was a political agreement with no formal legal status under the UNFCCC, it reflected
27 significant progress on several fronts and set in place the building blocks for the Paris Agreement,
28 namely: setting a goal of limiting global temperature increase to below 2°C; calling on all countries to
29 put forward mitigation pledges; establishing broad new terms for the reporting and verification of
30 countries’ actions; setting a goal of mobilising USD100 billion a year by 2020 from a wide variety of
31 sources, public and private, bilateral and multilateral, including alternative sources of finance; and,
32 calling for the establishment of a new Green Climate Fund and Technology Mechanism (Rogelj et al.
33 2010; Rajamani 2010; UNFCCC 2010a). One hundred and forty states endorsed the Copenhagen
34 Accord, with 85 countries entering pledges to reduce their emissions or constrain their growth by 2020
35 (Christensen and Olhoff 2019).

36 At COP 16 in Cancun in 2010, parties adopted a set of decisions termed the *Cancun Agreements* that
37 effectively formalised the core elements of the Copenhagen Accord, and the pledges states made, under
38 the UNFCCC. The Cancun Agreements were regarded as an interim arrangement through to 2020, and
39 parties left the door open to further negotiations, in line with negotiations launched in 2005, toward a
40 legally binding successor to the Kyoto Protocol (Freestone 2010; Liu 2011a). Collectively the G-20
41 states are on track to meeting the mid-level of their Cancun pledges, although there is uncertainty about
42 some individual pledges. However, there is significant gap between annual emissions expected under
43 full implementation of pledges and the level consistent with the 2°C goal (Christensen and Olhoff 2019).

44 At the 2011 Durban climate conference, parties launched negotiations for ‘a Protocol, another legal
45 instrument or agreed outcome with legal force’ with a scheduled end to the negotiations in 2015
46 (UNFCCC 2012, Dec. 1, para. 2). At the 2012 Doha climate conference, parties adopted a second

1 commitment period for the Kyoto Protocol, running from 2013-2020. The Doha amendment entered
 2 into force in 31 December 2020. Given the subsequent adoption of the Paris Agreement, the Kyoto
 3 Protocol is unlikely to continue beyond 2020 (Bodansky et al. 2017a). At the end of the compliance
 4 assessment period under the Kyoto Protocol, Annex B parties were in full compliance with their targets
 5 for the first commitment period; in some cases through the use of the Protocol’s flexibility mechanisms
 6 (Shishlov et al. 2016).

7 Although both the Kyoto Protocol and Paris Agreement are under the UNFCCC, they are generally seen
 8 as representing fundamentally different approaches to international cooperation on climate change
 9 (Held and Roger 2018; Falkner 2016b). The Paris Agreement has been characterised as a ‘decisive
 10 break’ from the Kyoto Protocol (Keohane and Oppenheimer 2016). Some note that the mitigation
 11 efforts under the Kyoto Protocol take the form of targets that, albeit based on national self-selection,
 12 were part of the multilateral negotiation process, whereas under the Paris Agreement parties make
 13 nationally determined contributions. The different approaches have been characterised by some as a
 14 distinction between a ‘top down’ and ‘bottom up’ approach (Bodansky and Rajamani 2016; Bodansky
 15 et al. 2016; Chan et al. 2016; Doelle 2016) but others disagree with such a characterisation pointing to
 16 continuities within the regime, for example, in terms of rules for reporting and review, and crossover
 17 and use of common institutional arrangements (Depledge 2017; Allan 2019). Some note, in any case,
 18 that the Kyoto Protocol’s core obligations are substantive obligations of result, while many of the Paris
 19 Agreement’s core obligations are procedural obligations, complemented by obligations of conduct
 20 (Rajamani 2016a; Mayer 2018a).

21 The differences between and continuities in the three treaties that comprise the UN climate regime are
 22 summarised in Table 14.3 below. The Kyoto targets apply only to Annex I parties, but the procedural
 23 obligations relating to NDCs in the Paris Agreement apply to all parties, with flexibilities in relation to
 24 some obligations for Least Developed Countries (LDCs), Small Island Developing States (SIDS), and
 25 developing countries that need it in light of their capacities. The Kyoto targets are housed in its Annex
 26 B, therefore requiring a formal process of amendment for revision, whereas the Paris NDCs are located
 27 in an online registry that is maintained by the Secretariat, but to which parties can upload their own
 28 NDCs. The Kyoto Protocol allows Annex B parties to use three market-based mechanisms – the Clean
 29 Development Mechanism (CDM), Joint Implementation and International Emissions Trading – to fulfil
 30 a part of their GHG targets. The Paris Agreement recognizes that parties may choose to cooperate
 31 voluntarily on markets, in the form of cooperative approaches under Article 6.2, and a mechanism with
 32 international oversight under Article 6.4, subject to guidance and rules that are yet to be adopted. These
 33 rules relate to integrity and accounting (La Hoz Theuer et al. 2019). Article 5 also provides explicit
 34 endorsement of REDD+. The Kyoto Protocol contains an extensive reporting and review process,
 35 backed by a compliance mechanism. This mechanism includes an enforcement branch, to ensure
 36 compliance, and sanction non-compliance (through the withdrawal of benefits such as participation in
 37 market-based mechanisms), with its national system requirements, and GHG targets. By contrast, the
 38 Paris Agreement relies on informational requirements and flows to enhance the clarity of NDCs, and to
 39 track progress in the implementation and achievement of NDCs.

40
 41 **Table 14.3 Continuities in and differences between the UNFCCC, Paris Agreement and the Kyoto**
 42 **Protocol**

Feature	UNFCCC	Kyoto Protocol	Paris Agreement
Objective	To stabilize GHGs in the atmosphere at a level that would prevent	Primarily mitigation-focused (although in pursuit of the	Mitigation in line with a long-term temperature goal, adaptation and finance goals, as well as

	dangerous anthropogenic interference with the climate system, in a time frame to protect food security, enable natural ecosystem adaptability and permit economic development in a sustainable manner	UNFCCC objective)	sustainable development and equity (also, in pursuit of the UNFCCC objective)
Architecture	‘Framework’ agreement with agreement on principles such as CDDRRC, division of countries into Annexes, with different groups of countries with differentiated commitments.	Differentiated targets, based on national offers submitted to the multilateral negotiation process, and multilaterally negotiated common metrics	Nationally determined contributions subject to transparency, multilateral consideration of progress, common metrics in inventories and accounting.
Coverage of mitigation-related commitments	Annex I Parties with a GHG stabilization goal, all Parties to take policies and measures	UNFCCC Annex I/Kyoto Annex B parties only	All parties
Targets	GHG stabilization goal for Annex I parties (‘quasi target’)	Legally binding, differentiated mitigation targets inscribed in treaty	Non-binding (in terms of results) contributions incorporated in parties’ NDCs, and provisions including those relating to highest possible ambition, progression and common but differentiated responsibilities and respective capabilities, in light of different national circumstances
Timetable	Aim to return to 1990 levels of GHGs by 2000	Two commitment periods (2008-2012; 2013-2020)	Initial NDCs for timeframes from 2020 running through 2025 or 2030 with new or updated NDCs every five years, and

			encouragement to submit long-term low GHG emission development strategies
Adaptation	Parties to cooperate in preparing for adaptation to the impacts of climate change	Parties to formulate and implement national adaptation measures, share of proceeds from CDM to fund adaptation	Qualitative global goal on adaptation to enhance adaptive capacity and resilience, and reduce vulnerability, parties to undertake national adaptation planning and implementation
Loss and Damage	Not covered	Not covered	Cooperation and facilitation to enhance understanding, action and support for loss and damage, including through the Warsaw International Mechanism on Loss and Damage under the UNFCCC
Transparency	National communications from parties, with differing content and set to differing timeframes for different categories of parties	Reporting and review – Annex B parties only	Enhanced transparency framework and five-yearly global stocktake for a collective assessment of progress towards goals – all parties
Support	Annex II commitments relating to provision of finance, development and transfer of technology to developing countries	Advances UNFCCC Annex II commitments relating to provision of finance, development and transfer of technology to developing countries	Enhances reporting in relation to support, expands the base of donors, and tailors support to the needs and capacities of developing countries
Implementation	National implementation, communication on implementation	Market mechanisms (international emissions trading, joint implementation, CDM)	Voluntary cooperation on mitigation (through market-based and non-market approaches); encouragement of REDD+ (guidance and rules under negotiation)

Compliance	Multilateral consultative process, never adopted	Compliance committee with facilitative and enforcement branches; sanctions for non-compliance	Committee to promote compliance and facilitate implementation; no sanctions

2 **14.3.1.2 Negotiating Context and Dynamics**

3 The 2015 Paris Agreement was negotiated in a starkly different geopolitical context to that of the 1992
 4 UNFCCC and the 1997 Kyoto Protocol (Streck and Terhalle 2013; Ciplet et al. 2015). The ‘rupturing
 5 binary balance of superpowers’ of the 1980s had given way to a multipolar world with several
 6 distinctive trends: emerging economies began challenging US dominance (Ciplet et al. 2015);
 7 industrialised countries’ emissions peaked in the 2010s and started declining, while emissions from
 8 emerging economies began to grow (Falkner 2019); the EU stretched eastwards and became
 9 increasingly supra-national (Kinley et al. 2020); disparities within the group of developing countries
 10 increased (Ciplet et al. 2015); and the role of non-state actors in mitigation efforts has grown more
 11 salient (Bäckstrand et al. 2017; Kuyper et al. 2018b; Falkner 2019). The rise of emerging powers, many
 12 of whom now have ‘veto power’, however, some noted, did not detract from the unequal development
 13 and inequality at the heart of global environmental politics (Hurrell and Sengupta 2012).

14 In this altered context, unlike in the 1990s when the main cleavages were between the EU and the US
 15 (Hurrell and Sengupta 2012), US-China ‘great power politics’ came to be seen as determinative of
 16 outcomes in the climate change negotiations (Terhalle and Depledge 2013). The US-China joint
 17 announcement (Whitehouse 2014), for instance, before the 2014 Lima climate conference, brokered the
 18 deal on differentiation that came to be embodied in the Paris Agreement (Ciplet and Roberts 2017;
 19 Rajamani 2016a). Others have identified, on the basis of economic standing, political influence, and
 20 emissions levels, three influential groups - the first comprising the US with Japan, Canada, and Russia,
 21 the second comprising the EU and the third comprising China, India and Brazil (Brenton 2013). The
 22 emergence of the Major Economies Fora (MEF), among other climate clubs (discussed in Section
 23 14.2.2) reflects this development (Brenton 2013). It also represents a ‘minilateral’ forum, built on a
 24 recognition of power asymmetries, in which negotiating compromises are politically tested and fed into
 25 multilateral processes (Falkner 2016a).

26 Beyond these countries, in the decade leading up to the Paris climate negotiations, increasing
 27 differences within the group of developing countries divided the 134-strong developing country alliance
 28 of the G-77/China into several interest-based coalitions (Vihma et al. 2011; Bodansky et al. 2017b). A
 29 division emerged between the vulnerable least developed and small island states on the one side and
 30 rapidly developing economies, the BASIC (Brazil, South Africa, India and China) on the other, as the
 31 latter are ‘decidedly not developed but not wholly developing’ (Hochstetler and Milkoreit 2013). This
 32 ‘fissure’ in part led to the High Ambition Coalition in Paris between vulnerable countries and the more
 33 progressive industrialised countries (Ciplet and Roberts 2017). A division also emerged between the
 34 BASIC countries (Hurrell and Sengupta 2012), that each have distinctive identities and positions
 35 (Hochstetler and Milkoreit 2013). In the lead up to the Paris negotiations, China and India formed the
 36 Like-Minded Developing Countries (LMDCs) with OPEC and the Bolivarian Alliance for the Peoples
 37 of our Americas (ALBA) countries, to resist the erosion of differentiation in the regime. Yet, the
 38 ‘complex and competing’ identities of India and China, with differing capacities, challenges and self-
 39 images, have also influenced the negotiations (Rajamani 2017; Ciplet and Roberts 2017). Other
 40 developing countries’ coalitions also played an important role in striking the final deal in Paris. The

1 Alliance of Small Island States (AOSIS), despite their lack of structural power, played a leading role,
2 in particular in relation to the inclusion of the 1.5°C long term temperature goal in the UN climate
3 regime (Agueda Corneloup and Mol 2014; Ourbak and Magnan 2018). The Association of the Latin
4 American and Caribbean Countries (AILAC) that emerged in 2012 also played a decisive role in
5 fostering ambition (Edwards et al. 2017; Watts and Depledge 2018).

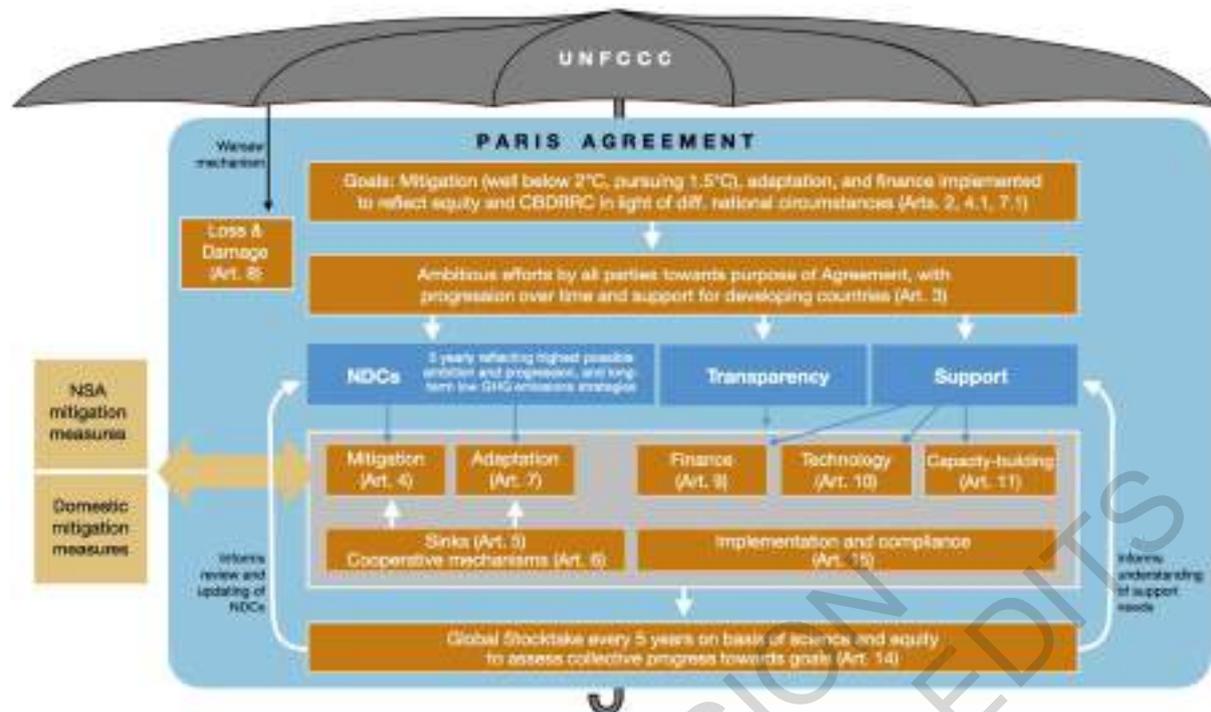

6 Leadership is essential to reaching international agreements and overcoming collective action problems
7 (Parker et al. 2015). The Paris negotiations were faced, as a reflection of the multipolarity that had
8 emerged, with a ‘fragmented leadership landscape’ with the US, EU, and China being perceived as
9 leaders at different points in time and to varying degrees (Parker et al. 2014; Karlsson et al. 2012). Small
10 island states are also credited with demonstrating ‘moral leadership’ (Agueda Corneloup and Mol 2014),
11 and non-state and sub-national actors are beginning to be recognised as pioneers and leaders (Wurzel
12 et al. 2019). There is also a burgeoning literature on the emergence of diffused leadership and the
13 salience of followers (Busby and Urpelainen 2020; Parker et al. 2014).

14 It is in the context of this complex, multipolar and highly differentiated world - with a heterogeneity of
15 interests, constraints and capacities, increased contestations over shares of the carbon and development
16 space, as well as diffused leadership - that the Paris Agreement was negotiated. This context
17 fundamentally influenced the shape of the Paris Agreement in particular on issues relating to its
18 architecture, ‘legalisation’ (Karlsson 2017) and differentiation (Bodansky et al. 2017b; Kinley et al. 2020),
19 all of which are discussed below.

20

21 **14.3.2 Elements of the Paris Agreement relevant to mitigation**

22 The 2015 Paris Agreement to the UNFCCC, which entered into force on 4 November 2016, and has
23 192 Parties as of date, is at the centre of international cooperative efforts for climate change mitigation
24 and adaptation in the post-2020 period. Although its legal form was heavily disputed, especially in the
25 initial part of its four-year negotiating process (Rajamani 2015; Maljean-Dubois and Wemaëre 2016;
26 Klein et al. 2017; Bodansky et al. 2017b), the Paris Agreement is a treaty containing provisions of
27 differing levels of “bindingness” (Bodansky 2016; Rajamani 2016b; Oberthür and Bodle 2016). The
28 legal character of provisions within a treaty, and the extent to which particular provisions lend
29 themselves to assessments of compliance or non-compliance, depends on factors such as the normative
30 content of the provision, the precision of its terms, the language used, and the oversight mechanisms in
31 place (Werksman 2010; Bodansky 2015; Oberthür and Bodle 2016; Rajamani 2016b). Assessed on
32 these criteria, the Paris Agreement contains the full spectrum of provisions, from hard to soft law
33 (Pickering et al. 2019; Rajamani 2016b) and even ‘non-law’, provisions that do not have standard-
34 setting or normative content, but which play a narrative-building and context-setting role (Rajamani
35 2016b). The Paris Agreement, along with the UNFCCC and the Kyoto Protocol, can be interpreted in
36 light of the customary international law principle of harm prevention according to which states must
37 exercise due diligence in seeking to prevent activities within their jurisdiction from causing
38 extraterritorial environmental harm (Mayer 2016a; Maljean-Dubois 2019). The key features of the Paris
39 Agreement are set out in Box 14.1.

1
2 **Figure 14.1 Key features of the Paris Agreement. Arrows illustrate the interrelationship between the**
3 **different features of the Paris Agreement, in particular between the Agreement’s goals, required actions**
4 **(through NDCs, support (finance, technology and capacity-building), transparency framework and global**
5 **stocktake process. The figure also represents points of interconnection with domestic mitigation**
6 **measures, whether taken by state parties or by non-state actors (NSAs). This figure is illustrative rather**
7 **than exhaustive of the features and interconnections.**

8 Figure 14.1 illustrates graphically the key features of the Paris Agreement. The Paris Agreement is
9 based on a set of binding procedural obligations requiring parties to ‘prepare, communicate, and
10 maintain’ ‘nationally determined contributions’ (NDCs) (UNFCCC 2015a, Art. 4.2) every five years
11 (UNFCCC 2015a, Art. 4.9). These obligations are complemented by: (1) an ‘ambition cycle’ that
12 expects parties, informed by five-yearly global stocktakes (Art 14), to submit successive NDCs
13 representing a progression on their previous NDCs (UNFCCC 2015a; Bodansky et al. 2017b), and (2)
14 an ‘enhanced transparency framework’ that places extensive informational demands on parties, tailored
15 to capacities, and establishes review processes to enable tracking of progress towards achievement of
16 NDCs (Oberthür and Bodle 2016). In contrast to the Kyoto Protocol with its internationally inscribed
17 targets and timetable for emissions reduction for developed countries, the Paris Agreement contains
18 nationally determined contributions embedded in an international system of transparency and
19 accountability for all countries (Doelle 2016; Maljean-Dubois and Wemaëre 2016) accompanied by a
20 shared global goal, in particular in relation to a temperature limit.

21 **14.3.2.1 Context and purpose**

22 The preamble of the Paris Agreement lists several factors that provide the interpretative context for the
23 Agreement (Carazo 2017; Bodansky et al. 2017b), including a reference to human rights. The human
24 rights implications of climate impacts garnered particular attention in the lead up to Paris (Duyck 2015;
25 Mayer 2016b). In particular, the Human Rights Council, its special procedures mechanisms, and the
26 Office of the High Commissioner for Human Rights, through a series of resolutions, reports, and
27 activities, advocated a rights-based approach to climate impacts, and sought to integrate this approach
28 in the climate change regime. The Paris Agreement’s preambular recital on human rights recommends
29 that parties, ‘when taking action to address human rights’, take into account ‘their respective obligations
30 on human rights’ (UNFCCC 2015a, preambular recital 14), a first for an environmental treaty (Knox
31 2016). The ‘respective obligations’ referred to in the Paris Agreement could potentially include those

1 relating to the right to life (UNGA 1948, Art. 3, 1966, Art. 6), right to health (UNGA 1966b, Art. 12),
2 right to development, right to an adequate standard of living, including the right to food (UNGA 1966b,
3 Art. 11), which has been read to include the right to water and sanitation (CESCR 2002, 2010), the right
4 to housing (CESCR 1991), and the right to self-determination, including as applied in the context of
5 indigenous peoples (UNGA 1966a,b, Art. 1). In addition, climate impacts contribute to displacement
6 and migration (Mayer and Crépeau 2016; McAdam 2016), and have disproportionate effects on women
7 (Pearse 2017). There are differing views on the value and operational impact of the human rights recital
8 in the Paris Agreement (Adelman 2018; Boyle 2018; Duyck et al. 2018; Rajamani 2018; Savaresi 2018;
9 Knox 2019). Notwithstanding proposals from some parties and stakeholders to mainstream and
10 operationalise human rights in the climate regime post-Paris (Duyck et al. 2018), and references to
11 human rights in COP decisions, the 2018 Paris Rulebook contains limited and guarded references to
12 human rights (Duyck 2019; Rajamani 2019) (see Section 14.5.1.2). In addition to the reference to human
13 rights, the preamble also notes the importance of ‘ensuring the integrity of all ecosystems, including
14 oceans and the protection of biodiversity’ which provides opportunities for integrating and
15 mainstreaming other environmental protections.

16 The overall purpose of international cooperation through the Paris Agreement is to enhance the
17 implementation of the UNFCCC, including its objective of stabilising atmospheric GHG concentrations
18 ‘at a level that would prevent dangerous anthropogenic interference with the climate system’ (UNFCCC
19 1992, Art. 2). The Paris Agreement aims to strengthen the global response to the threat of climate
20 change, in the context of sustainable development and efforts to eradicate poverty, by inter alia
21 ‘[h]olding the increase in the global average temperature to well below 2°C above pre-industrial levels
22 and pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial levels’ (UNFCCC
23 2015a, Art. 2(1)(a)). There is an ongoing structured expert dialogue under the UNFCCC in the context
24 of the second periodic review of the long-term global goal (the first was held between 2013-2015) aimed
25 at enhancing understanding of the long-term global goal, pathways to achieving it, and assessing the
26 aggregate effect of steps taken by parties to achieve the goal.

27 Some authors interpret the Paris Agreement’s temperature goal as a single goal with two inseparable
28 elements, the well below 2°C goal pressing towards 1.5°C (Rajamani and Werksman 2018), but others
29 interpret the goal as a unitary one of 1.5°C with minimal overshoot (Mace 2016). Yet others interpret
30 1.5° C as the limit within the long-term temperature goal, and that it ‘signals an increase in both the
31 margin and likelihood by which warming is to be kept below 2°C (Schleussner et al. 2016). Although
32 having a long-term goal has clear advantages, the literature highlights the issue of credibility, given the
33 lengthy timeframe involved (Urpelainen 2011), and stresses that future regulators may have incentives
34 to relax current climate plans, which could have a significant effect on the achieved GHG stabilisation
35 level (Gerlagh and Michielsen 2015).

36 As the risks of adverse climate impacts, even with a ‘well below’ 2°C increase, are substantial, the
37 purpose of the Paris Agreement extends to increasing adaptive capacity and fostering climate resilience
38 (UNFCCC 2015a, Art. 2(1)(b)), as well as redirecting investment and finance flows (UNFCCC 2015a,
39 Art (2)(1)(c); Thorgeirsson 2017). The finance and adaptation goals are not quantified in the Paris
40 Agreement itself but the temperature goal and the pathways they generate may, some argue, enable a
41 quantitative assessment of the resources necessary to reach these goals, and the nature of the impacts
42 requiring adaptation (Rajamani and Werksman 2018). The decision accompanying the Paris Agreement
43 resolves to set a new collective quantified finance goal prior to 2025 (not explicitly limited to developed
44 countries), with USD100 billion yr⁻¹ as a floor (UNFCCC 2016a, para. 53; Bodansky et al. 2017b).
45 Article 2 also references sustainable development and poverty eradication, and thus implicitly
46 underscores the need to integrate the SDGs in the implementation of the Paris Agreement (Sindico
47 2016).

1 The Paris Agreement's purpose is accompanied by an expectation that the Agreement 'will be'
2 implemented to 'reflect equity and the principle of common but differentiated responsibilities and
3 respective capabilities (CBDRRC), in the light of different national circumstances' (UNFCCC 2015a,
4 Art. 2.2). This provision generates an expectation that parties will implement the agreement to reflect
5 CBDRRC, and is not an obligation to do so (Rajamani 2016a). Further, the inclusion of the term 'in
6 light of different national circumstances' introduces a dynamic element into the interpretation of the
7 CBDRRC principle. As national circumstances evolve, the application of the principle will also evolve
8 (Rajamani 2016a). This change in the articulation of the CBDRRC principle is reflected in the shifts in
9 the nature and extent of differentiation in the climate change regime (Maljean-Dubois 2016; Rajamani
10 2016a; Voigt and Ferreira 2016a), including through a shift towards 'procedurally-oriented
11 differentiation' for developing countries (Huggins and Karim 2016).

12 Although NDCs are developed by individual state parties, the Paris Agreement requires that these are
13 undertaken by parties 'with a view' to achieving the Agreement's purpose and collectively 'represent a
14 progression over time' (UNFCCC 2015a, Art. 3). The Paris Agreement also encourages parties to align
15 the ambition of their NDCs with the temperature goal through the Agreement's 'ambition cycle', thus
16 imparting operational relevance to the temperature goal (Rajamani and Werksman 2018).

17 Article 4.1 contains a further non-binding requirement that parties 'aim' to reach global peaking of
18 GHG 'as soon as possible' and to undertake rapid reductions thereafter to achieve net zero GHG
19 emissions 'in the second half of the century'. Some argue this implies a need to reach net zero GHG
20 emissions in the third quarter of the 21st century (Rogelj et al. 2015; IPCC 2018b; ch2, table 2.4; cross-
21 chapter box 3 on net zero targets). To reach net zero CO₂ around 2050, in the short-term global net
22 human-caused CO₂ emissions would need to fall by about 45% - 60% from 2010 levels by 2030 (IPCC
23 2018b). Achieving the Paris Agreement's Article 4.1 aim potentially implies imply that global warming
24 will peak and then follow a gradually declining path, potentially to below 1.5°C warming (Rogelj et al.
25 2021).

26 Albeit non-binding, Article 4.1 has acted as a catalyst for several national net-zero GHG targets, as well
27 net zero CO₂ and GHG targets across local governments, sectors, businesses, and other actors (Day et
28 al. 2020). There is a wide variation in the targets that have been adopted – in terms of their legal
29 character (policy statement, executive order or national legislation), scope (GHGs or CO₂) and coverage
30 (sectors or economy-wide). National net-zero targets could be reflected in the long-term strategies that
31 states are urged to submit under Article 4.19, but only a few states have submitted such strategies thus
32 far. The Paris Rulebook, agreed at the Agreement's first meeting of the parties in 2018, further
33 strengthens the operational relevance of the temperature goal by requiring parties to provide information
34 when submitting their NDCs on how these contribute towards achieving the objective identified in
35 UNFCCC Article 2, and Paris Agreement Articles 2.1 (a) and 4.1 (UNFCCC 2019b, Annex I, para. 7),
36 Parties could in this context include information on how their short-term actions align with their long-
37 term net zero GHG or CO₂ targets thereby enhancing the credibility of their long-term goals.

38 At last count 131 countries had adopted or had net zero targets (whether of carbon or GHG) in the
39 pipeline, covering 72% of global emissions. If these targets are fully implemented some estimate that
40 this could bring temperature increase down to 2-2.4°C by 2100 as compared to current policies which
41 are estimated to lead to a temperature increase of 2.9–3.2 °C, and NDCs submitted to the Paris
42 Agreement which are estimated to lead to a temperature increase of 2.4-2.9°C (Höhne et al. 2021).

43 It is worth noting that Article 4.1 recognizes that 'peaking will take longer for developing countries'
44 and that the balance between emissions and removals needs to be on the 'basis of equity, and in the
45 context of sustainable development and efforts to eradicate poverty.' This suggests that not all countries
46 are expected to reach net zero GHG emissions at the same time, or in the same manner. If global cost-
47 effective 1.5 °C and 2 °C scenarios from integrated assessment models are taken, without applying an
48 equity principle, the results suggest that domestic net zero GHG and CO₂ emissions would be reached

1 a decade earlier than the global average in Brazil and the USA and later in India and Indonesia (van
2 Soest et al. 2021). By contrast if equity principles are taken into account, countries like Canada and the
3 EU would be expected to phase-out earlier than the cost-optimal scenarios indicate, and countries like
4 China and Brazil could phase out emissions later, as well as other countries with lower per-capita
5 emissions (van Soest et al. 2021). Some suggest that the application of such fairness considerations
6 could bring forward the net zero GHG date for big emitting countries by up to 15 to 35 years as
7 compared to the global least-cost scenarios (Lee et al. 2021b). In any case, reaching net-zero GHG
8 emissions requires to some extent the use of carbon dioxide removal (CDR) methods as there are
9 important sources of non-CO₂ GHGs, such as methane and nitrous oxide, that cannot be fully eliminated
10 resorting to carbon dioxide removal (CDR) methods (IPCC 2018b). However, there are divergent views
11 on different CDR methods, policy choices determine the degree to which and the type of CDR methods
12 that are considered and there is a patchwork of applicable regulatory instruments. There are also
13 uncertainties and governance challenges associated with CDR methods which render tracking progress
14 against net zero GHG emissions challenging (Mace et al. 2021). Researchers have noted that given the
15 key role of CDR in net-zero targets and 1.5 °C compatible pathways, and the fact that it presents
16 ‘significant costs to current and future generations,’ it is important to consider what an equitable
17 distribution of CDR might look like (UNFCCC 2019c; Day et al. 2020; Lee et al. 2021b).

18 **14.3.2.2 NDCs, progression and ambition**

19 Each party to the Paris Agreement has a procedural obligation to ‘prepare, communicate and maintain’
20 successive NDCs ‘that it intends to achieve.’ Parties have a further procedural obligation to ‘pursue
21 domestic mitigation measures’ (UNFCCC 2015a, Art. 4.2). These procedural obligations are coupled
22 with an obligation of conduct to make best efforts to achieve the objectives of NDCs (Rajamani 2016a;
23 Mayer 2018b). Many states have adopted climate policies and laws, discussed in Chapter 13, and
24 captured in databases (LSE 2020).

25 The framing and content of NDCs is thus largely left up to parties, although certain normative
26 expectations apply. These include developed country leadership through these parties undertaking
27 economy-wide absolute emissions reduction targets (UNFCCC 2015a, Art. 4.4), as well as
28 ‘progression’ and ‘highest possible ambition’ reflecting ‘common but differentiated responsibilities and
29 respective capabilities in light of different national circumstances’ (Art 4.3). There is ‘a firm
30 expectation’ that for every five-year cycle a party puts forward a new or updated NDC that is ‘more
31 ambitious than their last’ (Rajamani 2016a). While what represents a party’s highest possible ambition
32 and progression is not prescribed by the Agreement or elaborated in the Paris Rulebook (Rajamani and
33 Bodansky 2019), these obligations could be read to imply a due diligence standard (Voigt and Ferreira
34 2016b).

35 In communicating their NDCs every five years (UNFCCC 2015a, Art. 4.9), all parties have an
36 obligation to ‘provide the information necessary for clarity, transparency and understanding’ (UNFCCC
37 2015a, Art. 4.8). These requirements are further elaborated in the Paris Rulebook (Doelle 2019;
38 UNFCCC 2019b). This includes requirements — for parties’ second and subsequent NDCs — to
39 provide quantifiable information on the reference point e.g. base year, reference indicators and target
40 relative to the reference indicator (UNFCCC 2019b, Annex I, para 1). It also requires parties to provide
41 information on how they consider their contribution ‘fair and ambitious in light of different national
42 circumstances’, and how they address the normative expectations of developed country leadership,
43 progression and highest possible ambition (UNFCCC 2019b, Annex I, para 6). However, parties are
44 required to provide the enumerated information only ‘as applicable’ to their NDC (UNFCCC 2019b,
45 Annex I, para 7). This allows parties to determine the informational requirements placed on them
46 through their choice of NDC. In respect of parties’ first NDCs or NDCs updated by 2020, such
47 quantifiable information ‘may’ be included, ‘as appropriate’, signalling a softer requirement, although
48 parties are ‘strongly encouraged’ to provide this information (UNFCCC 2019b, Annex I, para 9).

1 Parties' first NDCs submitted to the provisional registry maintained by the UNFCCC Secretariat vary
2 in terms of target type, reference year or points, time frames, and scope and coverage of GHGs. A
3 significant number of NDCs include adaptation, and several NDCs have conditional components, for
4 instance, being conditional on the use of market mechanisms or on the availability of support (UNFCCC
5 2016b). There are wide variations across NDCs. Uncertainties are generated through interpretative
6 ambiguities in the assumptions underlying NDCs, (Rogelj et al. 2017). According to the assessment in
7 this report, current policies lead to median global GHG emissions of 63 GtCO₂-eq with a full range of
8 57-70 by 2030 and unconditional and conditional NDCs to 59 (55-65) and 56 (52-61) GtCO₂-eq,
9 respectively (Chapter 4, Table 4.1). Many omit important mitigation sectors, provide little detail on
10 financing implementation, and are not effective in meeting assessment and review needs (Pauw et al.
11 2018). Although, it is estimated that the land-use sector could contribute as much as 20% of the full
12 mitigation potential of all the intended NDC targets (Forsell et al. 2016), there are variations in how
13 the land-use component is included, and the related information provided, leading to large uncertainties
14 on whether and how these will contribute to the achievement of the NDCs (Grassi et al. 2017;
15 Obergassel et al. 2017a; Benveniste et al. 2018; Fyson and Jeffery 2019; Forsell et al. 2016). All these
16 variations make it challenging to aggregate the efforts of countries and compare them to each other
17 (Carraro 2016). Although parties attempted to discipline the variation in NDCs, including whether they
18 could be conditional, through elaborating the 'features' of NDCs in the Rulebook, no agreement was
19 possible on this. Thus, parties continue to enjoy considerable discretion in the formulation of NDCs
20 (Rajamani and Bodansky 2019; Weikmans et al. 2020).

21 There are several approaches to evaluating NDCs incorporating indicators such as CO₂ emissions, GDP,
22 energy intensity of GDP, CO₂ per energy unit, CO₂ intensity of fossil fuels, and share of fossil fuels in
23 total energy use (Peters et al. 2017). However, some favour approaches that use metrics beyond
24 emissions such as infrastructure investment, energy demand, or installed power capacity (Iyer et al.
25 2017; Jeffery et al. 2018). One approach is to combine the comparison of aggregate NDC emissions
26 using Integrated Assessment Model scenarios with modelling of NDC scenarios directly, and carbon
27 budget analyses (Jeffery et al. 2018). Another approach is to engage in a comprehensive assessment of
28 multiple indicators that reflect the different viewpoints of the parties under the UNFCCC (Aldy et al.
29 2017; Höhne et al. 2018). These different approaches are described in greater depth in Chapter 4, section
30 4.2.2.

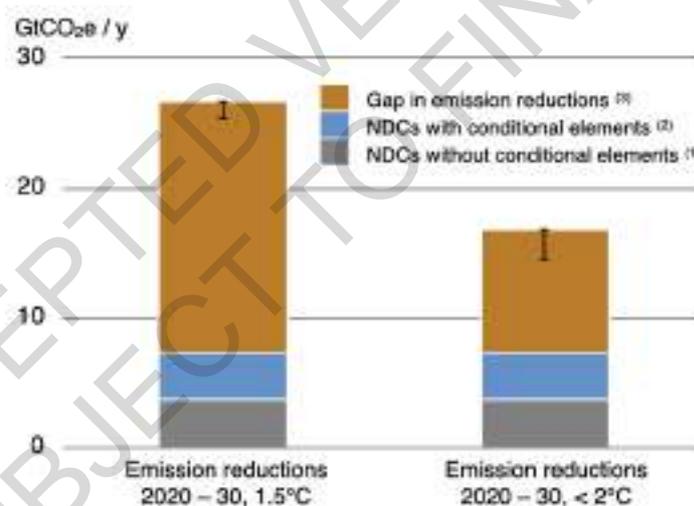

31 It is clear, however, that the NDCs communicated by parties for the 2020-2030 period are insufficient
32 to achieve the temperature goal (den Elzen et al. 2016; Rogelj et al. 2016; Schleussner et al. 2016;
33 Robiou du Pont and Meinshausen 2018; UNEP 2018a; Alcaraz et al. 2019; UNEP 2019, 2020), and the
34 emissions gap is larger than ever (Christensen and Olhoff 2019) (see Chapter 4). The IPCC 1.5°C Report
35 notes that pathways that limit global warming to 1.5°C with no or limited overshoot show up to 40-50%
36 reduction of total GHG emissions from 2010 levels by 2030, and that current pathways reflected in the
37 NDCs are consistent with cost-effective pathways that result in a global warming of about 3°C by 2100
38 ((IPCC 2018b) SPM, D.1.1). Analysis by the UNFCCC Secretariat of the second round of those NDCs
39 submitted until into October 2021 suggests that 'total global GHG emission level, taking into account
40 full implementation of all the latest NDCs (including their conditional elements), implies possibility of
41 global emissions peaking before 2030'. However, such total global GHG emission level in 2030 is still
42 expected to be 15.9% above the 2010 level. This 'implies an urgent need for either a significant increase
43 in the level of ambition of NDCs between now and 2030 or a significant overachievement of the latest
44 NDCs, or a combination of both.' (UNFCCC 2021a).

45 Many NDCs with conditional elements may not be feasible as the conditions are not clearly defined and
46 existing promises of support are insufficient (Pauw et al. 2020). Moreover, 'leadership by conditional
47 commitments' (when some states promise to take stronger commitments if others do so as well), and
48 the system of pledge-and-review, may lead to decreasing rather than deeper contributions over time

1 (Helland et al. 2017). Some note, however, that many of the NDCs are conservative and may be
 2 overachieved, that NDCs may be strengthened over time as expected under the Paris Agreement, and
 3 there are significant non-state actions that have not been adequately captured in the NDCs (Höhne et
 4 al. 2017). Further, if all NDCs with and without conditional elements are implemented, net land use,
 5 land use change and forestry emissions will decrease in 2030 compared to 2010 levels, but large
 6 uncertainties remain on how Parties estimate, project and account for emissions and removals from this
 7 sector (Forsell et al. 2016; Fyson and Jeffery 2019). According to the estimates in Table 4.3 (Chapter
 8 4), communicated unconditional commitments imply about a 7% reduction of world emissions by 2030,
 9 in terms of Kyoto GHGs, compared to a scenario where only current policies are in place. If conditional
 10 commitments are also included, the reduction in world emissions by 2030 would be about 12%.

11 In this context, it should be noted that many NDCs have been formulated with conditional elements,
 12 and such NDCs require international cooperation on finance, technology and capacity-building
 13 (Kissinger et al. 2019), potentially including through Article 6 in the form of bilateral agreements and
 14 market mechanisms (UNFCCC 2016b). More broadly, some argue that there is a ‘policy inconsistency’
 15 between the facilitative, ‘bottom up’ architecture of the Paris Agreement, and both the setting of the
 16 long-term temperature goal, as well as expectations that it will be delivered (Geden 2016b). As Figure
 17 14.2 shows, there is a large share of additional effort needed to reach a 1.5°C compatible path by 2030
 18 (and even a 2°C compatible path). International coordination and cooperation are crucial in enhancing
 19 the ambition of current pledges, as countries will be more willing to increase their ambition if matched
 20 by other countries (coordination) and if cost-minimising agreements between developed and developing
 21 countries, through Article 6 and other means, are fully developed (cooperation) (Sælen 2020).

22

23

24 **Figure 14.2 The role of international cooperation in the reductions in annual emissions by 2030 needed to**
 25 **follow a 1.5°C (respectively < 2°C) cost-effective path from 2020 onwards. The figure represents the**
 26 **additional contribution of pledges included in the NDCs over current policies at the global level, and the**
 27 **remaining gap in emission reductions needed to move from current policies to cost-effective long-term**
 28 **mitigation pathways for limiting warming to 1.5°C with low (<0.1°C) overshoot (50% chance),**
 29 **respectively for limiting warming to 2°C (66% chance). Median values are used, showing the confidence**
 30 **interval for the total effort. See Figure 1 in Cross-Chapter Box 4, and Tables 4.2 and 4.3 for details. (1)**

31 **The grey share represents NDCs with abatement efforts pledged without any conditions (called**
 32 **“unconditional” in the literature). They are based mainly on domestic abatement actions, although**
 33 **countries can use international cooperation to meet their targets. (2) The blue share represents NDCS**
 34 **with conditional components. They require international cooperation, for example bilateral agreements**
 35 **under article 6, financing or monetary and/or technological transfers. (3) The remaining gap in emission**
 36 **reductions – the orange share – can potentially be achieved through national and international actions.**

1 **International coordination of more ambitious efforts promotes global ambition and international**
2 **cooperation provides the cost-saving basis for more ambitious NDCs.**

3
4 **14.3.2.3 NDCs, fairness and equity**

5 The Paris Agreement encourages Parties, while submitting their NDCs, to explain how these are ‘fair
6 and ambitious’ (UNFCCC 2015a, Art. 4.8 read with UNFCCC 2016a, para. 27). The Rulebook obliges
7 Parties to provide information on ‘fairness considerations, including reflecting on equity’ as applicable
8 to their NDC (Rajamani and Bodansky 2019; UNFCCC 2019b paras 7a and 9, Annex, paras 6(a) and
9 (b)). Although equity within nations and between communities is also important, much of the literature
10 on fairness and equity in the context of NDCs focuses on equity between nations.

11 In the first round of NDCs, most Parties declared their NDCs as fair (Robiou du Pont et al. 2017). Their
12 claims, however, were largely unsubstantiated or drawn from analysis by in-country experts (Winkler
13 et al. 2018). At least some of the indicators Parties have identified in their NDCs as justifying the
14 ‘fairness’ of their contributions, such as a ‘small share of global emissions’, ‘cost-effectiveness’ and
15 assumptions that privilege current emissions levels (‘grandfathering’) are not, according to one group
16 of scholars, in accordance with principles of international environmental law (Rajamani et al. 2021).
17 Moreover, the NDCs reveal long-standing institutional divisions and divergent climate priorities
18 between Annex I and non-Annex I Parties, suggesting that equity and fairness concerns remain salient
19 (Stephenson et al. 2019). Fairness concerns also affect the share of carbon dioxide removal (CDR)
20 responsibilities for major emitters if they delay near-term mitigation action (Fyson et al. 2020).

21 It is challenging, however, to determine ‘fair shares’, and address fairness and equity in a world of
22 voluntary climate contributions (Chan 2016a), in particular, since these contributions are insufficient
23 (see above Section 14.3.2.2.). Self-differentiation in contributions has also led to fairness and equity
24 being discussed in terms of individual nationally determined contributions rather than between
25 categories of countries (Chan 2016a). In the climate change regime, one option is for Parties to provide
26 more rigorous information under the Paris Agreement to assess fair shares (Winkler et al. 2018), and
27 another is for Parties to articulate what equity principles they have adopted in determining their NDCs,
28 how they have operationalised these principles, and explain their mitigation targets in terms of the
29 portion of the appropriated global budget (Hales and Mackey 2018).

30 Equity is critical to addressing climate change, including through the Paris Agreement (Klinsky et al.
31 2017), however, since the political feasibility of developing equity principles within the climate change
32 regime is low, the onus is on mechanisms and actors outside the regime to develop these (Lawrence and
33 Reder 2019). Equity and fairness concerns are being raised in national and regional courts that are
34 increasingly being asked to determine if the climate actions pledged by states are adequate in relation
35 to their fair share (The Supreme Court of the Netherlands 2019; European Court of Human Rights 2020;
36 German Constitutional Court 2021), as it is only in relation to such a ‘fair share’ that the adequacy of a
37 state’s contribution can be assessed in the context of a global collective action problem (see chapter
38 13.5.5 for a discussion of national climate litigation). Some domestic courts have stressed that as climate
39 change is a global problem of cumulative impact, all emissions contribute to the problem regardless of
40 their relative size and there is a clear articulation under the UNFCCC and Paris Agreement for
41 developed countries to ‘take the lead’ in addressing GHG emissions (Preston 2020). Given the limited
42 avenues for multilateral determination of fairness, several researchers have argued that the onus is on
43 the scientific community to generate methods to assess fairness (Herrala and Goel 2016; Lawrence and
44 Reder 2019). Peer-to-peer comparisons also potentially create pressure for ambitious NDCs (Aldy et
45 al. 2017).

46 There are a range of options to assess or introduce fairness. These include: adopting differentiation in
47 financing rather than in mitigation (Gajevic Sayegh 2017); adopting a carbon budget approach (Hales

1 and Mackey 2018; Alcaraz et al. 2019), which may occur through the transparency processes (Hales
2 and Mackey 2018); quantifying national emissions allocations using different equity approaches,
3 including those reconciling finance and emissions rights distributions (Robiou du Pont et al. 2017);
4 combining equity concepts in a bottom-up manner using different sovereign approaches (Robiou du
5 Pont and Meinshausen 2018), using data on adopted emissions targets to find an ethical framework
6 consistent with the observed distribution (Sheriff 2019); adopting common metrics for policy
7 assessment (Bretschger 2017); and developing a template for organising metrics on mitigation effort -
8 emission reductions, implicit prices, and costs - for both ex ante and ex post review (Aldy et al. 2017).
9 The burden of agricultural mitigation can also be distributed using different approaches to effort sharing
10 (responsibility, capability, need, equal cumulative per-capita emissions) (Richards et al. 2018). Further,
11 there are temporal (inter-generational) and spatial (inter-regional) dimensions to the distribution of the
12 mitigation burden, with additional emissions reductions in 2030 improving both inter-generational and
13 inter-regional equity (Liu et al. 2016). Some of the equity approaches rely on ‘grandfathering’ as an
14 allocation principle, which some argue has led to ‘cascading biases’ against developing countries
15 (Kartha et al. 2018), and is morally ‘perverse’ (Caney 2011). While no country's NDC explicitly
16 supports the grandfathering approach, many countries describe as ‘fair and ambitious’ NDCs that assume
17 grandfathering as the starting point (Robiou du Pont et al. 2017). It is worth noting that the existence of
18 multiple metrics associated with a range of equity approaches, has implications for how the ambition
19 and ‘fair’ share of each state is arrived at, some average out multiple approaches and indicators (Hof et
20 al. 2012; Meinshausen et al. 2015; Robiou du Pont and Meinshausen 2018), others exclude indicators
21 and approaches that do not, in their interpretation, accord with principles of international environmental
22 law (Rajamani et al. 2021). One group of scholars have suggested that utilitarianism offers a ‘ethically
23 minimal and conceptually parsimonious’ benchmark that promotes equity, climate and development
24 (Budolfson et al. 2021).

25 *14.3.2.4 Transparency and accountability*

26 Although NDCs reflect a ‘bottom-up’, self-differentiated approach to climate mitigation actions, the
27 Paris Agreement couples this to an international transparency framework designed, among other things,
28 to track progress in implementing and achieving mitigation contributions (UNFCCC 2015a, Art. 13).
29 This transparency framework builds on the processes that already exist under the UNFCCC. The
30 transparency framework under the Paris Agreement is applicable to all Parties, although with flexibilities
31 for developing country Parties that need it in light of their capacities (Mayer 2019). Each Party is
32 required to submit a national inventory report, as well as ‘the information necessary to track progress
33 in implementing and achieving’ its NDC, (UNFCCC 2015a, Art. 13.7) biennially (UNFCCC 2016a,
34 para. 90). The Paris Rulebook requires all Parties to submit their national inventory reports using the
35 2006 IPCC Guidelines (UNFCCC 2019b, Annex, para. 20).

36 In relation to the provision of information necessary to track progress towards implementation and
37 achievement of NDCs, the Paris Rulebook allows each party to choose its own qualitative or
38 quantitative indicators (UNFCCC 2019k, Annex, para 65), a significant concession to national
39 sovereignty (Rajamani and Bodansky 2019). The Rulebook phases in common reporting requirements
40 for developed and developing countries (except LDCs and SIDS) at the latest by 2024 (UNFCCC
41 2019k, para. 3), but offers flexibilities in ‘scope, frequency, and level of detail of reporting, and in the
42 scope of the review’ for those developing countries that need it in light of their capacities (UNFCCC
43 2019k, Annex, para. 5). Some differentiation also remains for information on support provided to
44 developing countries (Winkler et al. 2017), with developed country parties required to report such
45 information biennially, while others are only ‘encouraged’ to do so (UNFCCC 2015a, Art. 9.7).

46 The information provided by Parties in biennial transparency reports and GHG inventories will undergo
47 technical expert review, which must include assistance in identifying capacity-building needs for
48 developing country parties that need it in light of their capacities. Each Party is also required to

1 participate in a ‘facilitative, multilateral consideration of progress’ of implementation and achievement
2 of its NDC. Although the aim of these processes is to expose each Party’s actions on mitigation to
3 international review, thus establishing a weak form of accountability for NDCs at the international level,
4 the Rulebook circumscribes the reach of these processes (Rajamani and Bodansky 2019). The technical
5 expert review teams are prohibited in mandatory terms from making ‘political judgments’ or reviewing
6 the ‘adequacy or appropriateness’ of a party’s NDC, domestic actions, or support provided (UNFCCC
7 2019k, Annex, para. 149). This, among other such provisions, has led some to argue that the scope and
8 practice of existing transparency arrangements reflects rather than mediates ongoing disputes around
9 responsibility, differentiation and burden sharing, and thus there is limited answerability through
10 transparency (Gupta and van Asselt 2019). There are also limits to the extent that the enhanced
11 transparency framework will reduce ambiguities, and associated uncertainties, for instance, in how
12 LULUCF is incorporated into the NDCs (Fyson and Jeffery 2019) and lead to increased ambition
13 (Weikmans et al. 2020). More broadly, there has been ‘weak’ translation of transparency norms into
14 accountability (Ciplet et al. 2018). Hence, the Paris Agreement’s effectiveness in ensuring NDCs are
15 achieved will depend on additional accountability pathways at the domestic level involving political
16 processes and civil society engagement (Jacquet and Jamieson 2016; van Asselt 2016; Campbell-
17 Duruflé 2018a; Karlsson-Vinkhuyzen et al. 2018).

18 **14.3.2.5 Global stocktake**

19 The Paris Agreement’s transparency framework is complemented by the global stocktake, which will
20 take place every five years (starting in 2023) and assess the collective progress towards achieving the
21 Agreement’s purpose and long-term goals (UNFCCC 2015a, Art. 14). The scope of the global stocktake
22 is comprehensive – covering mitigation, adaptation and means of implementation and support – and the
23 process is to be facilitative and consultative. The Paris Rulebook outlines the scope of the global
24 stocktake to include social and economic consequences and impacts of response measures, and loss and
25 damage associated with the adverse effects of climate change (UNFCCC 2019f, paras. 8-10).

26 The global stocktake is to occur ‘in the light of equity and the best available science.’ While the focus
27 of the global stocktake is on collective and not individual progress towards the goals of the Agreement,
28 the inclusion of equity in the global stocktake enables a discussion on equitable burden sharing
29 (Rajamani 2016a; Winkler 2020), and for equity metrics to be factored in (Robiou du Pont and
30 Meinshausen 2018). The Paris Rulebook includes consideration of the modalities and sources of inputs
31 for the global stocktake (UNFCCC 2019f, paras 1, 2, 13, 27, 31, 36h and 37g), which arguably will
32 result in equity being factored into the outcome of the stocktake (Winkler 2020). The Rulebook does
33 not, however, some argue, resolve the tension between the collective nature of the assessment that is
34 authorised by the stocktake and the individual assessments required to determine relative ‘fair share’
35 (Rajamani and Bodansky 2019; Zahar 2019).

36 The global stocktake is seen as crucial to encouraging parties to increase the ambition of their NDCs
37 (Huang 2018; Hermwille et al. 2019; Milkoreit and Haapala 2019) as its outcome ‘shall inform Parties
38 in updating and enhancing, in a nationally determined manner, their actions and support’ (Art 14.3)
39 (Rajamani 2016a; Friedrich 2017; Zahar 2019). The Rulebook provides for the stocktake to draw on a
40 wide variety of inputs sourced from a full range of actors, including ‘non-Party stakeholders’ (UNFCCC
41 2019f, para. 37). However, the Rulebook specifies that the global stocktake will be ‘a Party-driven
42 process’ (UNFCCC 2019f, para. 10), will not have an ‘individual Party focus’, and will include only
43 ‘non-policy prescriptive consideration of collective progress’ (UNFCCC 2019f, para. 14).

44 **14.3.2.6 Conservation of sinks and reservoirs, including forests**

45 Article 5 of the Paris Agreement calls for parties to take action to conserve and enhance sinks and
46 reservoirs of greenhouse gases, including biomass in terrestrial, coastal, and marine ecosystems, and
47 encourages countries to take action to support the REDD+ framework under the Convention. The
48 explicit inclusion of land use sector activities, including forest conservation, is potentially, while

1 cautiously, a ‘game changer’ as it encourages countries to safeguard ecosystems for climate mitigation
2 purposes (Grassi et al. 2017). Analyses of parties’ NDCs shows pledged mitigation from land use, and
3 forests in particular, provides a quarter of the emission reductions planned by parties and, if fully
4 implemented, would result in forests becoming a net sink of carbon by 2030 (Forsell et al. 2016; Grassi
5 et al. 2017).

6 A key action endorsed by Article 5 is REDD+, which refers to initiatives established under the
7 UNFCCC for reducing emissions from deforestation and forest degradation and the role of
8 conservation, sustainable management of forests and enhancement of forest carbon stocks in developing
9 countries. It remains an evolving concept and some identified weaknesses are being addressed,
10 including the issues of scale (project-based vs sub-national jurisdictional approach), problems with
11 leakage, reversal, benefit sharing, as well as safeguards against potential impacts on local and
12 indigenous communities. Nevertheless, REDD+ shows several innovations under the climate regime
13 with regard to international cooperation. The legal system for REDD+ manages to reconcile flexibility
14 (creating consensus) and legal security. It shows a high standard of effectiveness (Dellaux 2017).

15 Article 5.2 encourages parties to implement and support the existing framework for REDD+, including
16 through ‘results-based payments’ i.e. provision of financial payments for verified avoided or reduced
17 forest carbon emissions (Turnhout et al. 2017). The existing REDD+ framework set up under decisions
18 of the UNFCCC COP includes the Warsaw Framework for REDD+, which specifies modalities for
19 measuring, reporting and verifying (MRV) greenhouse gas emissions and removals. This provides an
20 essential tool for linking REDD+ activities to results-based finance (Voigt and Ferreira 2015).
21 Appropriate finance support for REDD+ is also considered critical to move from its inclusion in many
22 countries’ NDCs to implementation on the ground (Hein et al. 2018). Since public finance for REDD+
23 is limited, private sector participation is expected by some to leverage REDD+ (Streck and Parker 2012;
24 Henderson et al. 2013; Pistorius and Kiff 2015; Seymour and Busch 2016; Ehara et al. 2019). Article
25 5.2 also encourages parties’ support for ‘alternative policy approaches’ to forest conservation and
26 sustainable management such as ‘joint mitigation and adaptation approaches.’ It reaffirms the
27 importance of incentivising, as appropriate, non-carbon benefits associated with such approaches (e.g.
28 improvements in the livelihoods of forest-dependent communities, facilitating poverty reduction and
29 sustainable development). This provision, along with the support for non-market mechanisms in Article
30 6 (discussed below), is seen as an avenue for cooperative joint mitigation-adaptation and non-market
31 REDD+ activities with co-benefits for biodiversity conservation (Gupta and Dube 2018).

32 **14.3.2.7 Cooperative approaches**

33 Article 6 of the Paris Agreement provides for voluntary cooperative approaches. Its potential
34 importance in terms of project-based cooperation should be viewed against the background of key
35 lessons from the market-based mechanisms under the Kyoto Protocol, particularly the Clean
36 Development Mechanism (CDM). The CDM has been used for implementing bilateral strategies and
37 unilateral (non-market) actions for instance in India (Phillips and Newell 2013), hence arguably
38 covering all the mechanisms now included in Article 6 of the Paris Agreement. As we describe in
39 section 14.3.3.1, below, ex-post evaluation of the Kyoto market mechanisms, in particular the CDM,
40 have been at-best mixed. However, Article 6 goes beyond the project-based approach followed by the
41 CDM, as hinted by the emerging landscape of activities based on Article 6 (Greiner et al. 2020), such
42 as the bilateral treaty signed under the framework of Article 6 in October 2020 by Switzerland and Peru
43 (see section 14.4.4).

44 This experience from the CDM is relevant to the implementation of Article 6 (4) of the Paris Agreement.
45 It addresses a number of specific types of cooperative approaches, including those involving the use of
46 internationally transferred mitigation outcomes (ITMOs) towards NDCs, a ‘mechanism to contribute to
47 mitigation and support sustainable development’, and a framework for non-market approaches such as
48 many aspects of REDD+.

1 Article 6.1 recognises the role that cooperative approaches can play, on a voluntary basis, in
2 implementing parties' NDCs 'in order to allow for higher ambition' in their mitigation actions and to
3 promote sustainable development and environmental integrity. Article 6.2 indicates that ITMOs can
4 originate from a variety of sources, and that parties using ITMOs to achieve their NDCs shall promote
5 sustainable development, ensure environmental integrity, ensure transparency, including in governance,
6 and apply 'robust accounting' in accordance with CMA guidance to prevent double counting. While
7 this provision, unlike Article 17 of the Kyoto Protocol, does not create an international carbon market,
8 it enables parties to pursue this option should they choose to do so, for example, through the linking of
9 domestic or regional carbon markets (Marcu 2016; Müller and Michaelowa 2019). Article 6.2 could
10 also be implemented in other ways, including direct transfers between governments, linkage of
11 mitigation policies across two or more parties, sectoral or activity crediting mechanisms, and other
12 forms of cooperation involving public or private entities, or both (Howard 2017).

13 Assessments of the potential of Article 6.2 generally find that ITMOs are likely to result in cost
14 reductions in achieving mitigation outcomes, with the potential for such reductions to enhance ambition
15 and accelerate parties' progression of mitigation pledges across NDC cycles (Fujimori et al. 2016; Gao
16 et al. 2016; Mehling 2019). However, studies applying insights from the CDM highlight environmental
17 integrity risks associated with using ITMOs under the Paris Agreement given the challenges that the
18 diverse scope, metrics, types and timeframes of NDC targets pose for robust accounting (Schneider and
19 La Hoz Theuer 2019) and the potential for transfers of 'hot air' as occurred under the Kyoto Protocol
20 (La Hoz Theuer et al. 2019). These studies collectively affirm that robust governance on accounting for
21 ITMOs, and for reporting and review, will be critical to ensuring the environmental integrity of NDCs
22 making use of them (Mehling 2019; Müller and Michaelowa 2019).

23 Article 6.4 concerns the mitigation mechanism, with some similarities to the Kyoto Protocol's CDM.
24 Unlike the CDM, there is no restriction on which parties can host mitigation projects and which parties
25 can use the resulting emissions reductions towards their NDCs (Marcu 2016). This central mechanism
26 will operate under the authority and guidance of the CMA, and is to be supervised by a body designated
27 by the CMA (Marcu 2016).

28 The Article 6.4 central mechanism is intended to promote mitigation while fostering sustainable
29 development. The decision adopting the Paris Agreement specifies experience with Kyoto market
30 mechanisms as a basis for the new mitigation mechanism (UNFCCC 2016a, para. 37(f)). Compared
31 with the CDM under the Kyoto Protocol, the central mechanism has a more balanced focus on both
32 climate and development objectives, and a stronger political mandate to measure sustainable
33 development impact and to verify that the impacts are 'real, measurable, and long-term' (Olsen et al.
34 2018). There are also opportunities to integrate human rights into the central mechanism (Oberghassel et
35 al. 2017b; Calzadilla 2018). It is further subject to the requirement that it must deliver 'an overall
36 mitigation in global emissions,' which is framed by the general objectives of Article 6 for cooperation
37 to enhance ambition (Kreibich 2018).

38 Negotiations over rules to operationalise Article 6 have thus far proven intractable, failing to deliver
39 both at COP-24 in Katowice in 2018, where the rest of the Paris Rulebook was agreed, and in COP-25
40 in Madrid in 2019. Ongoing points of negotiation have included: whether to permit the carryover and
41 use of Kyoto CDM credits and AAUs into the Article 6.4 mechanism, whether to impose a mandatory
42 share of proceeds on Article 6.2 mechanism to fund adaptation, like for Article 6.4; and whether and
43 how credits generated under Article 6.4 should be subject to accounting rules under Article 6.2
44 (Michaelowa et al. 2020a).

45 **14.3.2.8 Finance flows**

46 Finance is the first of three means of support specified under the Paris Agreement to accomplish its
47 objectives relating to mitigation (and adaptation) (UNFCCC 2015a, Art. 14.1). This sub-section
48 discusses the provision made in the Paris Agreement for international cooperation on finance. Section

1 14.4.1 below considers broader cooperative efforts on public and private finance flows for climate
2 mitigation, including by multilateral development banks and through instruments such as green bonds.

3 As highlighted above, the objective of the Paris Agreement includes the goal of ‘[m]aking finance flows
4 consistent with a pathway towards low greenhouse gas emissions and climate-resilient development’
5 (UNFCCC 2015a, Art 2.1(c)). Alignment of financial flows, and in some cases provision of finance
6 will be critical to the achievement of many parties’ NDCs, particularly those that are framed in
7 conditional terms (Zhang and Pan 2016; Kissinger et al. 2019) (see further Chapter 15 on investment
8 and finance).

9 International cooperation on climate finance represents ‘a complex and fragmented landscape’ with a
10 range of different mechanisms and forums involved (Pickering et al. 2017; Roberts and Weikmans
11 2017). These include entities set up under the international climate change regime, such as the UNFCCC
12 financial mechanism, with the Global Environment Facility (GEF) and Green Climate Fund (GCF) as
13 operating entities; special funds, such as the Special Climate Change Fund, the Least Developed
14 Countries Fund (both managed by the GEF), and the Adaptation Fund established under the Kyoto
15 Protocol; the Standing Committee on Finance, a constituted body which assists the COP in exercising
16 its functions with respect to the UNFCCC financial mechanism; and other bodies outside of the
17 international climate change regime, such as the Climate Investment Funds (CIF) administered through
18 multilateral development banks (the role of these banks in climate finance is discussed further in Section
19 14.4.1 below).

20 Pursuant to decisions adopted at the Paris and Katowice conferences, parties agreed that the operating
21 entities of the financial mechanism – GEF and GCF – as well as the Special Climate Change Fund, the
22 Least Developed Countries Fund, the Adaptation Fund and the Standing Committee on Finance, all
23 serve the Paris Agreement (UNFCCC 2016a, paras 58 and 63, 2019e,g). The GCF, which became
24 operational in 2015, is the largest dedicated international climate change fund and plays a key role in
25 channelling financial resources to developing countries (Antimiani et al. 2017; Brechin and Espinoza
26 2017).

27 Much of the current literature on climate finance and the Paris Agreement focuses on the obligations of
28 developed countries to provide climate finance to assist the implementation of mitigation and adaptation
29 actions by developing countries. The principal provision on finance in the Paris Agreement is the
30 binding obligation on developed country parties to provide financial resources to assist developing
31 country parties (UNFCCC 2015a, Art 9.1). This provision applies to both mitigation and adaptation and
32 is in continuation of existing developed country parties’ obligations under the UNFCCC. This signals
33 that the Paris Agreement finance requirements must be interpreted in light of the UNFCCC (Yamineva
34 2016). The novelty introduced by the Paris Agreement is a further expansion in the potential pool of
35 donor countries as Article 9.2 encourages ‘other parties’ to provide or continue to provide such support
36 on a voluntary basis. However, ‘as part of the global effort, developed countries should continue to take
37 the lead in mobilising climate finance’, with a ‘significant role’ for public funds, and an expectation
38 that such mobilisation of finance ‘should represent a progression beyond previous efforts’ Beyond this
39 there are no new recognised promises (Ciplet et al. 2018). In the Paris Agreement parties formalized
40 the continuation of the existing collective mobilization goal to raise 100 billion a year through 2025 in
41 the context of meaningful mitigation actions and transparency on implementation. The Paris Agreement
42 decision also provided for the CMA by 2025 to set a new collective quantified goal from a floor of
43 USD100 billion yr, taking into account the needs and priorities of developing countries (UNFCCC
44 2016a, para. 53). This new collective goal on finance is not explicitly limited to developed countries
45 and could therefore encompass finance flows from developing countries’ donors (Bodansky et al.
46 2017b). Deliberations on setting a new collective quantified goal on finance is expected to be initiated
47 at COP26 in 2021 (UNFCCC 2019g,e; Zhang 2019).

1 It is widely recognised that the USD100 billion yr⁻¹ figure is a fraction of the broader finance and
2 investment needs of mitigation and adaptation embodied in the Paris Agreement (Peake and Ekins
3 2017). One estimate, based on a review of 160 (I)NDCs, suggests the financial demand for both
4 mitigation and adaptation needs of developing countries could reach USD474 billion yr⁻¹ by 2030
5 (Zhang and Pan 2016). The OECD reports that climate finance provided and mobilised by developed
6 countries was USD79.6 billion in 2019. This finance included four components: bilateral public,
7 multilateral public (attributed to developed countries), officially supported export credits and mobilised
8 private finance (OECD 2021) (See also Chapter 15.3.2, and Box 15.4).

9 More broadly, there is recognition of the need for better accounting, transparency and reporting rules
10 to allow evaluation of the fulfilment of finance pledges and the effectiveness of how funding is used
11 (Xu et al. 2016; Roberts et al. 2017; Jachnik et al. 2019; Roberts et al. 2021; Gupta and van Asselt
12 2019). There is also a concern about climate finance being new and additional though the Paris
13 Agreement does not make an explicit reference to it, nor is there a clear understanding of what
14 constitutes new and additional (UNFCCC 2018; Carty et al. 2020; Mitchell et al. 2021). Some authors
15 see the ‘enhanced transparency framework’ of the Paris Agreement (see Section 14.3.2.4 above), and
16 the specific requirements for developed countries to provide, biennially, indicative quantitative and
17 qualitative information as well as report on financial support and mobilisation efforts (Articles 9.5 and
18 9.7), as promising marked improvements (Weikmans and Roberts 2019), including for the fairness of
19 effort-sharing on climate finance provision (Pickering et al. 2015). Others offer a more circumspect
20 view of the transformative capability of these transparency systems (Ciplet et al. 2018).

21 The more limited literature focusing on the specific finance needs of developing countries, particularly
22 those expressed in NDCs conditional on international climate finance, suggests that once all countries
23 have fully costed their NDCs, the demand for (public and private) finance to support NDC
24 implementation is likely to be orders of magnitude larger than funds available from bilateral and
25 multilateral sources. For some sectors, such as forestry and land-use, this could leave ‘NDC ambitions
26 ... in a precarious position, unless more diversified options are pursued to reach climate goals’
27 (Kissinger et al. 2019). In addition, there is a need for fiscal policy reform in developing countries to
28 ensure international climate finance flows are not undercut by public and private finance supporting
29 unsustainable activities (Kissinger et al. 2019). During the 2018 Katowice conference, UNFCCC Parties
30 requested the Standing Committee on Finance to prepare, every four years, a report on the determination
31 of the needs of developing country Parties related to implementing the Convention and the Paris
32 Agreement, for consideration by parties at COP26 (UNFCCC 2019c).

33 **14.3.2.9 Technology development and transfer**

34 Technology development and transfer is the second of three ‘means of implementation and support’
35 specified under the Paris Agreement to accomplish its objectives relating to mitigation (and adaptation)
36 (UNFCCC 2015a, Art. 14.1). This sub-section discusses the provision made in the Paris Agreement for
37 international cooperation on technology development and transfer. Section 14.4.2 below considers
38 broader cooperative efforts on technology development and transfer under the UNFCCC. Both sections
39 complement the discussion in Chapter 16.6 on the role of international cooperation in fostering
40 transformative change.

41 The importance of technology as a means of implementation for climate mitigation obligations under
42 the Paris Agreement is evident from parties’ NDCs. Of the 168 NDCs submitted as of June 2019, 109
43 were expressed as conditional upon support for technology development and transfer, with 70 parties
44 requesting technological support for both mitigation and adaptation, and 37 parties for mitigation only
45 (Pauw et al. 2020). Thirty-eight LDCs (79%) and 29 SIDS made their NDCs conditional on technology
46 transfer, as did 50 middle-income countries (Pauw et al. 2020).

47 While technology is seen as a key means of implementation and support for Paris Agreement
48 commitments, the issue of technology development and the transfer of environmentally sound

1 technologies for climate mitigation was heavily contested between developed and developing countries
2 in the Paris negotiations, and these differences are likely to persist as the Paris Agreement is
3 implemented (Oh 2019). Contestations continued in negotiations for the Paris Rulebook, particularly
4 regarding the meaning of technological innovation, which actors should be supported, and how support
5 should be provided by the UNFCCC (Oh 2020a).

6 Article 10 of the Paris Agreement articulates a shared ‘long-term vision on the importance of fully
7 realising technology development and transfer in order to improve resilience to climate change and to
8 reduce greenhouse gas emissions’ (UNFCCC, 2015, Art. 10.1). All parties are required ‘to strengthen
9 cooperative action on technology development and transfer’ (UNFCCC, 2015, Art. 10.2). In addition,
10 support, including financial support, ‘shall be provided’ to developing country parties for the
11 implementation of Article 10, ‘including for strengthening cooperative action on technology
12 development and transfer at different stages of the technology cycle, with a view to achieving a balance
13 between support for mitigation and adaptation’ (UNFCCC, 2015, Art. 10.6). Available information on
14 efforts related to support on technology development and transfer for developing country parties is also
15 one of the matters to be taken into account in the global stocktake (UNFCCC, 2015, Art. 10.6) (see
16 Section 14.3.2.5 above).

17 The Paris Agreement emphasises that efforts to accelerate, encourage and enable innovation are ‘critical
18 for an effective long-term global response to climate change and promoting economic growth and
19 sustainable development’ and urges that they be supported, as appropriate, by the Technology
20 Mechanism and Financial Mechanism of the UNFCCC (UNFCCC, 2015, Art. 10.5). This support
21 should be directed to developing country parties ‘for collaborative approaches to research and
22 development, and facilitating access to technology, in particular for early stages of the technology cycle’
23 (UNFCCC, 2015, Art. 10.5). Inadequate support for R&D, particularly in developing countries, has
24 been identified in previous studies of technology interventions by international institutions as a key
25 technology innovation gap that might be addressed by the Technology Mechanism (Coninck and Puig
26 2015).

27 To support parties’ cooperative action, the Technology Mechanism, established in 2010 under the
28 UNFCCC (see further Section 14.4.2 below), will serve the Paris Agreement, subject to guidance of a
29 new ‘technology framework’ (UNFCCC, 2015, Art. 10.4). The latter was strongly advocated by the
30 African group in the negotiations for the Paris Agreement (Oh 2020a), and was adopted in 2018 as part
31 of the Paris Rulebook, with implementation entrusted to the component bodies of the Technology
32 Mechanism. The guiding principles of the framework are coherence, inclusiveness, a results-oriented
33 approach, a transformational approach and transparency. Its ‘key themes’ include innovation,
34 implementation, enabling environment and capacity-building, collaboration and stakeholder
35 engagement, and support (UNFCCC 2019e, Annex). A number of ‘actions and activities’ are elaborated
36 for each thematic area. These include: enhancing engagement and collaboration with relevant
37 stakeholders, including local communities and authorities, national planners, the private sector and civil
38 society organisations, in the planning and implementation of Technology Mechanism activities;
39 facilitating parties undertaking, updating and implementing technology needs assessments (TNAs) and
40 aligning these with NDCs; and enhancing the collaboration of the Technology Mechanism with the
41 Financial Mechanism for enhanced support for technology development and transfer. As regards TNAs,
42 while some developing countries have already used the results of their TNA process in NDC
43 development, other countries might benefit from following the TNA process, including its stakeholder
44 involvement, and multi-criteria decision analysis methodology, to strengthen their NDCs (Hofman and
45 van der Gaast 2019).

46 ***14.3.2.10 Capacity-building***

47 Together with finance, and technology development and transfer, capacity-building is the third of ‘the
48 means of implementation and support’ specified under the Paris Agreement (see UNFCCC 2015a, Art.

1 14.1). Capacity-building has primarily been implemented through partnerships, collaboration and
2 different cooperative activities, inside and outside the UNFCCC. This sub-section discusses the
3 provision made in the Paris Agreement for international cooperation on capacity-building. Section
4 14.4.3 below considers broader cooperative efforts on capacity-building within the UNFCCC.

5 In its annual synthesis report for 2018, the UNFCCC secretariat stressed the importance of capacity-
6 building for the implementation of the Paris Agreement and NDCs, with a focus on measures already
7 in place, regional and cooperative activities, and capacity-building needs for strengthening NDCs
8 (UNFCCC 2019h). Of the 168 NDCs submitted as of June 2019, capacity-building was the most
9 frequently requested type of support (113 of 136 conditional NDCs) (Pauw et al. 2020). The focus of
10 capacity-building activities is on enabling developing countries to take effective climate change action,
11 given that many developing countries continue to face significant capacity challenges, undermining
12 their ability to effectively or fully carry out the climate actions they intend to pursue (Dagnet et al.
13 2016). Content analysis of NDCs shows that capacity-building for adaptation is prioritised over
14 mitigation for developing countries, with the element of capacity-building most indicated in NDCs
15 being research and technology (Khan et al. 2020). In addition, developing countries' needs for
16 education, training and awareness-raising for climate change mitigation and adaptation feature
17 prominently in NDCs, particularly those of LDCs (Khan et al. 2020). Differences are evident though
18 between capacity-building needs expressed in the NDCs of LDCs (noting that Khan et al.'s review was
19 limited to NDCs in English) compared with those of upper-middle income developing countries as
20 categorised by the World Bank (World Bank 2021); the latter have more focus on mitigation with an
21 emphasis on technology development and transfer (Khan et al. 2020).

22 The Paris Agreement urges all parties to cooperate to enhance the capacity of developing countries to
23 implement the Agreement (UNFCCC 2015a, Art. 11.3), with a particular focus on LDCs and SIDS
24 (UNFCCC 2015a, Art. 11.1). Developed country parties are specifically urged to enhance support for
25 capacity-building actions in developing country Parties (UNFCCC 2015a, Art. 11.3). Article 12 of the
26 Paris Agreement addresses cooperative measures to enhance climate change education, training, public
27 awareness, public participation and public access to information, which can also be seen as elements of
28 capacity-building (Khan et al. 2020). Under the Paris Rulebook, efforts related to the implementation
29 of Article 12 are referred to as 'Action for Climate Empowerment' and parties are invited to develop
30 and implement national strategies on this topic, taking into account their national circumstances
31 (UNFCCC 2019i, para. 6). Actions to enhance climate change education, training, public awareness,
32 public participation, public access to information, and regional and international cooperation may also
33 be taken into account by parties in the global stocktake process under Article 14 of the Paris Agreement
34 (UNFCCC 2019i, para. 9).

35 Under the Paris Agreement, capacity-building can take a range of forms, including: facilitating
36 technology development, dissemination and deployment; access to climate finance; education, training
37 and public awareness; and the transparent, timely and accurate communication of information
38 (UNFCCC 2015a, Art. 11.1; see also 14.3.2.4 on 'Transparency' above). Principles guiding capacity-
39 building support are that it should be: country-driven; based on and responsive to national needs;
40 fostering country ownership of parties at multiple levels; guided by lessons learned; and an effective,
41 iterative process that is participatory, cross-cutting and gender-responsive (UNFCCC 2015a, Art. 11.2).
42 Parties undertaking capacity-building for developing country parties must 'regularly communicate on
43 these actions or measures.' Developing countries parties have a soft requirement ('should') to
44 communicate progress made on implementing capacity-building plans, policies, actions or measures to
45 implement the Paris Agreement (UNFCCC 2015a, Art. 11.4).

46 Article 11.5 provides that capacity-building activities 'shall be enhanced through appropriate
47 institutional arrangements to support the implementation of this Agreement, including the appropriate
48 institutional arrangements established under the Convention that serve this Agreement'. The COP

1 decision accompanying the Paris Agreement established the Paris Committee on Capacity-building,
2 with the aim to ‘address gaps and needs, both current and emerging, in implementing capacity-building
3 in developing country Parties and further enhancing capacity-building efforts, including with regard to
4 coherence and coordination in capacity-building activities under the Convention’ (UNFCCC 2016a,
5 para. 71). The activities of the Committee are discussed further in Section 14.4.3 below. The relevant
6 COP decision also established the Capacity Building Initiative for Transparency (UNFCCC 2016a,
7 para. 84), which is managed by the GEF and designed to support developing country parties in meeting
8 the reporting and transparency requirements under Article 13 of the Paris Agreement (Robinson 2018).

9 Studies on past capacity-building support for climate mitigation offer some lessons for ensuring
10 effectiveness of arrangements under the Paris Agreement. For example, Umemiya et al. (2020) suggest
11 the need for a common monitoring system at the global level, and evaluation research at the project
12 level to achieve more effective capacity building support. Khan et al. (2020) articulate ‘four key pillars’
13 of a sustainable capacity-building system for implementation of NDCs in developing countries:
14 universities in developing countries as institutional hubs; strengthened civil society networks and
15 partnerships; long-term programmatic finance support; and consideration of a capacity-building
16 mechanism under the UNFCCC – paralleling the Technology Mechanism – to marshal, coordinate and
17 monitor capacity-building activities and resources.

18 **14.3.2.11 Implementation and compliance**

19 The Paris Agreement establishes a mechanism to facilitate implementation and promote compliance
20 under Article 15. This mechanism is to operate in a transparent, non-adversarial and non-punitive
21 manner (Voigt 2016; Campbell-Duruflé 2018b; Oberthür and Northrop 2018) that distinguishes it from
22 the more stringent compliance procedures of the Kyoto Protocol’s Enforcement branch. The Paris
23 Rulebook elaborated the modalities and procedures for the implementation and compliance mechanism,
24 specifying the nature and composition of the compliance committee, the situations triggering its
25 procedures, and the facilitative measures it can apply, which include a ‘finding of fact’ in limited
26 situations, dialogue, assistance and recommendations (UNFCCC 2019e). The compliance committee is
27 focused on ensuring compliance with a core set of binding procedural obligations (UNFCCC 2019j,
28 Annex, Para. 22). This compliance committee, characterised as ‘one of its kind’ and an ‘an important
29 cornerstone’ of the Agreement’s legitimacy, effectiveness and longevity (Zihua et al. 2019), is designed
30 to facilitate compliance rather than penalise non-compliance.

32 **START BOX 4.1 HERE**

33 **Box 14.1 Key features of the Paris Agreement relevant to mitigation.**

34 The Paris Agreement’s overall aim is to strengthen the global response to the threat of climate change,
35 in the context of sustainable development and efforts to eradicate poverty. This aim is explicitly linked
36 to enhancing implementation of the UNFCCC, including its objective in Article 2 of stabilising
37 greenhouse gas emissions at a level that would ‘prevent dangerous anthropogenic interference with the
38 climate system’. The Agreement sets three goals:

- 39 1. *Temperature*: holding the global average temperature increase to well below 2°C above pre-
40 industrial levels and pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial
41 levels.
- 42 2. *Adaptation and climate resilience*: increasing the ability to adapt to the adverse impacts of climate
43 change and foster climate resilience and low greenhouse gas emissions development, in a manner
44 that does not threaten food production.

1 3. *Finance*: making finance flows consistent with a pathway towards low greenhouse gas emissions
2 and climate-resilient development.

3 In order to achieve the long-term temperature goal, parties aim to reach global peaking of emissions as
4 soon as possible, recognising that peaking will take longer for developing countries, and then to
5 undertake rapid reductions in accordance with the best available science. This is designed to reach
6 global net zero GHG emissions in the second half of the century, with the emissions reductions effort
7 to be determined on the basis of equity and in the context of sustainable development and efforts to
8 eradicate poverty. In addition, implementation of the Agreement as a whole is expected to reflect equity
9 and parties' common but differentiated responsibilities and respective capabilities, in light of different
10 national circumstances.

11 The core mitigation commitments of parties under the Paris Agreement centre on preparing,
12 communicating and maintaining successive 'nationally determined contributions' (NDCs), the contents
13 of which countries determine for themselves. All parties must have NDCs and pursue domestic
14 mitigation measures with the aim of achieving the objectives of their NDCs, but parties NDCs are
15 neither subject to a review of adequacy (at an individual level) nor to legally binding obligations of
16 result. The compliance mechanism is correspondingly facilitative.

17 The Paris Agreement establishes a global goal on adaptation, and recognises the importance of averting,
18 minimising and addressing loss and damage associated with the adverse effects of climate change.

19 The efficacy of the Paris Agreement in achieving its goals is therefore dependent upon at least three
20 additional elements:

21 1. *Ratcheting of NDCs*: Parties must submit a new or updated NDC every 5 years that is in line with
22 the Paris Agreement's expectations of progression over time and the party's highest possible
23 ambition, reflecting common but differentiated responsibilities and respective capabilities in light
24 of different national circumstances.

25 2. *Enhanced transparency framework*: Parties' actions to implement their NDCs are subject to
26 international transparency and review requirements, which will generate information that may also
27 be used by domestic constituencies and peers to pressure governments to increase the ambition of
28 their NDCs.

29 3. *Collective global stocktake*: The global stocktake undertaken every 5 years, starting in 2023, will
30 review the collective progress of countries in achieving the Paris Agreement's goals, in light of
31 equity and best available science. The outcome of the global stocktake informs parties in updating
32 and enhancing their subsequent NDCs.

33 These international processes establish an iterative ambition cycle for the preparation, communication,
34 implementation and review of NDCs.

35 For developing countries, the Paris Agreement recognises that increasing mitigation ambition and
36 realising long-term low-emissions development pathways can be bolstered by the provision of financial
37 resources, capacity building, and technology development and transfer. In continuation of existing
38 obligations under the Convention, developed countries are obliged to provide financial assistance to
39 developing countries with respect to mitigation and adaptation. The Paris Agreement also recognizes
40 that Parties may choose to voluntarily cooperate in the implementation of their NDCs to allow for higher
41 ambition in their mitigation and adaptation actions and to promote sustainable development and
42 environmental integrity.

14.3.3 Effectiveness of the Kyoto Protocol and the Paris Agreement

14.3.3.1 Ex-post assessment of the Kyoto Protocol's effects

Previous assessment reports have assessed the Kyoto Protocol with respect to each of the criteria identified in this chapter. However, at the time of AR5, it was premature to assess the impact of Kyoto on emissions, as this data had not been entirely compiled yet. Since AR5, a number of studies have done so. Chapter 2 of this report lists 24 countries that have sustained absolute emissions reductions for at least a decade, of which 20 are countries that had Kyoto targets for the first commitment period. Most studies have concluded that Kyoto did cause emissions reductions. Such studies find a positive, statistically significant impact on emission reductions in Annex I countries (Kim et al. 2020), Annex B countries (Grunewald and Martínez-Zarzoso 2012; Kumazawa and Callaghan 2012; Grunewald and Martínez-Zarzoso 2016; Maamoun 2019), or all countries respectively (Aichele and Felbermayr 2013; Iwata and Okada 2014). Overall, countries with emission reduction obligations emit on average less CO₂ than similar countries without emission reduction obligations – with estimates ranging from 3-50% (Grunewald and Martínez-Zarzoso 2012, 2016). Maamoun (2019) estimates that the Kyoto Protocol reduced GHG emissions of Annex B countries by 7% on average below a no-Kyoto scenario over 2005 - 2012. Aichele and Felbermayr (2013) conclude that Kyoto reduced CO₂ and GHG emissions by 10% compared to the counterfactual. By contrast, Almer and Winkler (2017) find no evidence for binding emission targets under Kyoto inducing significant and lasting emission reductions for any of the Annex B or non-Annex B countries. The authors identify both negative and positive associations between Kyoto and emissions for several countries in several years, but no coherent picture emerges. Hartl (2019) calculates a Kyoto leakage share in global carbon dioxide trade of 4.3% for 2002-2009.

In terms of transformative potential, the Kyoto Protocol has been found to increase international patent applications for renewable energy technologies, especially in the case of solar energy technologies and especially in countries with more stringent emission reduction targets, and has even led to an increase in patent applications in developing countries not obliged to reduce emissions under Kyoto (Miyamoto and Takeuchi 2019). Kyoto also had a positive and statistically significant impact on the cost-effectiveness of renewable energy projects, as well as renewable energy capacity development as it stimulated the introduction of domestic renewable energy policies (Liu et al. 2019).

The issue of institutional strength of Kyoto has been analysed by many authors, and much of this has been assessed in previous assessment reports. Since AR5, several papers question the environmental efficacy of the Kyoto Protocol based on its institutional design (Rosen 2015; Kuriyama and Abe 2018). Particular attention has focused on Kyoto's market mechanisms (Erickson et al. 2014; Kollmuss et al. 2015).

As described in previous IPCC reports and above, the 1997 Kyoto Protocol included three international market-based mechanisms. These operated among Annex I Parties (i.e. International Emissions Trading and Joint Implementation) and between Annex I Parties and non-Annex I countries (i.e. the CDM) (Grubb et al. 2014; World Bank 2018). Joint Implementation led to limited volumes of emissions credit transactions, mostly from economies in transition but also some Western European countries; International Emissions Trading also led only to limited transaction volumes (Shishlov et al. 2016).

Of the Kyoto Protocol's mechanisms, the CDM market has led to a greater amount of activity, with a 'gold rush' period between 2005 and 2012. The main buyer of CDM credits were private companies surrendering them within the European Union (EU) Emissions Trading System (ETS). Once the EU tightened its rules and restricted the use of CDM credits in 2011, there was a sharp drop in the price of CDM credits in 2012. This price never recovered, as the demand for CDM was very weak after 2012, in part because of the difficulties encountered in securing the entry into force of the Doha Amendment (Michaelowa et al. 2019b).

1 Assessing the effectiveness of Kyoto's market mechanisms is challenging, and the results have been
2 mixed. (Aichele and Felbermayr 2013; Iwata and Okada 2014; Kuriyama and Abe 2018). Kuriyama
3 and Abe (2018) assessed emission reduction quantities taking into account heightened criteria for
4 additionality. They identified annual energy-related emissions reductions of 49 MtCO_{2e} y⁻¹ flowing
5 from the CDM, and non-energy related emissions reductions of 177 MtCO_{2e} y⁻¹. Others have pointed
6 to issues associated with non-energy related emission reductions that suggest the latter estimate may be
7 of questionable reliability, while also noting that regulatory tightening led later CDM projects to
8 perform better with respect to the additionality criterion (Michaelowa et al. 2019b). The CDM's
9 contribution to capacity building in some developing countries has been identified as possibly its most
10 important achievement (Spalding-Fecher et al. 2012; Gandenberger et al. 2015; Murata et al. 2016;
11 Dong and Holm Olsen 2017; Lindberg et al. 2018; Xu et al. 2016). There is evidence that the CDM
12 lowered compliance costs for Annex 1 countries by at least USD3.6 billion (Spalding-Fecher et al.
13 2012). In host countries, the CDM led to the establishment of national approval bodies and the
14 development of an ecosystem of consultants and auditors (Michaelowa et al. 2019b) .

15 On the negative side, there are numerous findings that the CDM, especially at first, failed to lead to
16 additional emissions cuts in host countries, meaning that the overall effect of CDM projects was to raise
17 global emissions. Cames et al. (2016) concluded that over 70% of CDM projects led to emissions
18 reductions that were likely less than projected, including the absence of additional reductions, while
19 only 7% of projects led to actual additional emissions reductions that had a high likelihood of meeting
20 or exceeding the ex-ante estimates. The primary reason the authors gave was the associated with the
21 low price for CDM credits; this meant that the contribution of the CDM to project finance was
22 negligible, suggesting that most CDM projects would have been built anyway. A meta-analysis of ex-
23 post studies of global carbon markets, which include the CDM, found net combined effects on emission
24 to be negligible (Green 2021). Across, the board, CDM projects have been criticised for lack of
25 'additionality', problems of baseline determination, uneven geographic coverage (Michaelowa and
26 Michaelowa 2011a; Cames et al. 2016; Michaelowa et al. 2019b), as well as failing to address human
27 rights concerns (Schade and Obergassel 2014).

28 ***14.3.3.2 Effectiveness of the Paris Agreement***

29 Given the comparatively recent conclusion of the Paris Agreement, evidence is still being gathered to
30 assess the effectiveness of the Paris Agreement in practice, in particular, since its long-term
31 effectiveness hinges on states communicating more ambitious nationally determined contributions in
32 successive cycles over time. Assessments of the Paris Agreement on paper are necessarily speculative
33 and limited by the lack of credible counterfactuals. Despite these limitations, numerous assessments
34 exist of the potential for international cooperation under the Paris Agreement to advance climate change
35 mitigation.

36 These assessments are mixed and reflect uncertainty over the outcomes the Paris Agreement will
37 achieve (Christoff 2016; Cléménçon 2016; Young 2016; Dimitrov et al. 2019; Raiser et al. 2020;
38 Keohane and Oppenheimer 2016). There is a divide between studies that do not expect a positive
39 outcome from the Paris Agreement and those that do. The former base this assessment on factors such
40 as: a lack of clarity in the expression of obligations and objectives; a lack of concrete plans collectively
41 to achieve the temperature goal; extensive use of soft law (i.e. non legally-binding) provisions; limited
42 incentives to avoid free-riding; and the Agreement's weak enforcement provisions (Allan 2019), as well
43 as US non-cooperation under the Trump administration and the resulting gap in mitigation, finance and
44 governance (Bang et al. 2016; Spash 2016; Tulkens 2016; Chai et al. 2017; Lawrence and Wong 2017;
45 Thompson 2017; Barrett 2018; Kemp 2018). Studies expecting a positive outcome emphasise factors
46 such as: the breadth of participation enabled by self-differentiated NDCs; the 'logic' of domestic climate
47 policies driving greater national ambition; the multiplicity of actors engaged by the Paris Agreement's
48 facilitative architecture; the falling cost of low-carbon technologies; provision for financial, technology

1 and capacity-building support to developing country parties; possibilities for voluntary cooperation on
2 mitigation under Article 6; and the potential for progressive ratcheting up of parties' pledges over time
3 fostered by transparency of reporting and international scrutiny of national justifications of the
4 'fairness' of contributions (Caparrós 2016; Morgan and Northrop 2017; Urpelainen and Van de Graaf
5 2018; Hale 2020; Tørstad 2020; Chan 2016a; Falkner 2016b; Victor 2016). Turning to the assessment
6 criteria articulated in this chapter, the following preliminary assessments of the Paris Agreement can be
7 made.

8 In relation to the criterion of *environmental effectiveness*, the Paris Agreement exceeds the Kyoto
9 Protocol in terms of coverage of GHGs and participation of states in mitigation actions. In terms of
10 coverage of GHGs, the Kyoto Protocol limits its coverage to a defined basket of gases identified in its
11 Annex A (Carbon dioxide (CO₂), Methane (CH₄), Nitrous oxide (N₂O), Hydrofluorocarbons (HFCs),
12 Perfluorocarbons (PFCs), Sulphur hexafluoride (SF₆), as well as nitrogen trifluoride (NF₃)). The Paris
13 Agreement does not specify the coverage of gases, thus parties may cover the full spectrum of GHGs
14 in their NDCs as encouraged by the accounting provisions in Annex II to Decision 18/CMA.1 (or
15 conversely choose to exclude important mitigation sectors) and there is also the possibility to include
16 other pollutants such as short-lived climate forcers like black carbon. Article 4.4 calls on developed
17 countries to undertake economy-wide emissions reduction targets with the expectation that developing
18 country parties will also move to introduce these over time. Moreover, the Paris Agreement makes
19 express reference to Parties taking action to conserve and enhance 'sinks and reservoirs of greenhouse
20 gases' (Article 5). As under the UNFCCC and Kyoto Protocol, this allows for coverage of AFOLU
21 emissions, both CO₂ and emissions of other Kyoto Annex A gases, as well as other forms of carbon
22 dioxide removal, including methane (Pekkarinen 2020). A few countries, particularly LDCs, include
23 quantified non-CO₂ emissions reductions from the agricultural sector in their NDCs, and many others
24 include agriculture in their economy-wide targets (Richards et al. 2018). Some studies find that
25 agricultural development pathways with mitigation co-benefits can deliver 21–40% of needed
26 mitigation for the 'well below 2°C' limit, thus necessitating 'transformative technical and policy
27 options' (Wollenberg et al. 2016). Other studies indicate that broader 'natural climate solutions,
28 including forests, can provide 37% of the cost-effective CO₂ mitigation needed through 2030 for a more
29 than 66% chance of holding warming to below 2°C' (Griscom et al. 2017).

30 As the estimates in Table 4.3 (Chapter 4) demonstrate, communicated unconditional NDCs, if achieved,
31 lead to a reduction of about 7% of world emissions by 2030 in relation to the Kyoto GHGs, and NDCs
32 with conditional elements increase this reduction to about 12% (den Elzen et al. 2016). Although there
33 are uncertainties in the extent to which countries will meet the conditional elements of their NDCs, the
34 experience with the Cancun pledges has been positive, as countries will collectively meet their pledges
35 by 2020, and even individual pledges will be met in most cases, although arguably helped by the
36 COVID-19 pandemic (UNEP 2020). In any case, the main challenge that remains is to close the
37 emissions gap, the difference between what has been pledged and what is needed to achieve by 2030 to
38 reach a 1.5° C compatible path (respectively 2° C) (Roelfsema et al. 2020; UNEP 2020, see also Cross-
39 chapter Box 4 in Chapter 4). In terms of participation of states in mitigation actions, the Paris
40 Agreement performs better than the Kyoto Protocol. The latter contains mitigation targets only for
41 developed countries listed in its Annex B, while the Paris Agreement extends binding procedural
42 obligations in relation to mitigation contributions to all states. It is noted, however, that the Paris
43 Agreement represented a weakening of commitments for those industrialised countries that were parties
44 to the Kyoto Protocol, although a strengthening for those that were not, and for developing countries
45 (Oberthür and Groen 2020). Finally, some analysts have suggested that the recent proliferation of
46 national mid-century net-zero targets – currently 127 countries have considered or adopted such targets
47 – can be attributed, at least in part, to participation in the Paris Agreement and having agreed to its
48 Article 4 (Climate Action Tracker 2020a; Day et al. 2020).

1 In relation to the criterion of *transformative potential*, there is, as yet, limited empirical data or
2 theoretical analysis on which to assess the Paris Agreement's transformative potential. The IPCC's
3 1.5°C report concluded that pathways limiting global warming to 1.5°C would require systems
4 transitions that are 'unprecedented in terms of scale' (IPCC 2018b). There is limited evidence to suggest
5 that this is underway, although there are arguments made that Paris has the right structure to achieve
6 this. The linking of the UNFCCC financial apparatus, including the GCF, to the Paris Agreement, and
7 the provisions on technology support and capacity-building, provide potential avenues for promoting
8 increased investment flows into low-carbon technologies and development pathways, as (Labordena et
9 al. 2017) show in the case of solar energy development in Africa. Similarly, Kern and Rogge (2016)
10 argue that the Paris Agreement's global commitment towards complete decarbonisation may play a
11 critical role in accelerating underlying system transitions, by sending a strong signal as to the actions
12 needed by national governments and other international support. Victor et al. (2019) argue that
13 international cooperation that enhances transformative potential needs to operate at the sectoral level,
14 as the barriers to transformation are highly specific to each sector; the Paris Agreement's broad
15 consensus around a clear level of ambition sends a strong signal on what is needed in each sector, but
16 on its own will do little unless bolstered with sectoral-specific action (Geels et al. 2019). On the less
17 optimistic side, it is noted that the extent of the 'investment signal' sent by the Agreement to business
18 is unclear (Kemp 2018), and it is also unclear to what extent the Paris Agreement is fostering investment
19 in break-through technologies. United States non-cooperation from 2017 to 2020 posed a significant
20 threat to adequate investment flows through the GCF (Chai et al. 2017; Urpelainen and Van de Graaf
21 2018).

22 In relation to the criterion of *distributive outcomes*, the Paris Agreement performs well in some respects
23 but less well in others, and its performance relative to the Kyoto Protocol is arguably lower in respect
24 of some indicators such as industrialised country leadership, and differentiation in favour of developing
25 countries. While the Kyoto Protocol implemented a multilaterally agreed burden sharing arrangement
26 set out in the UNFCCC and reflected in Annex-based differentiation in mitigation obligations, the Paris
27 Agreement relies on NDCs, accompanied by self-assessments of the fairness of these contributions;
28 some of these do not accord with equity principles of international environmental law, although it is
29 worth noting that the Kyoto Protocol was also not fully consistent with such principles. At present,
30 mechanisms in the Paris Agreement for promoting equitable burden-sharing and evaluating the fairness
31 of parties' contributions are undefined, although numerous proposals have been developed in the
32 literature (Ritchie and Reay 2017; Herrala and Goel 2016; Robiou du Pont et al. 2017; Alcaraz et al.
33 2019; Sheriff 2019) (discussed in Section 14.3.2.3, above). Zimm and Nakicenovic (2020) analysed the
34 first set of NDCs, and concluded that they would result in a decrease in the inequality of per capita
35 emissions across countries. In relation to other indicators such as the provision of support, the
36 distributive outcomes of the Paris Agreement are dependent on the availability of support through
37 mechanisms such as the GCF to meet the mitigation and adaptation financing needs of developing
38 countries (Antimiani et al. 2017; Chan et al. 2018). One study suggests that the implementation of the
39 emissions reduction objectives stated in the NDCs implies trade-offs with poverty reduction efforts
40 needed to achieve SDGs (Campagnolo and Davide 2019), while other studies offer evidence that the
41 immediate economic, environmental, and social benefits of mitigation in line with developing countries'
42 NDCs exceed those NDCs' costs, and ultimately align the the SDGs (Antwi-Agyei et al. 2018; Vandyck
43 et al. 2018; Caetano et al. 2020) (see Chapter 17). In relation to the promotion of co-benefits the Paris
44 Agreement has enhanced mechanisms for promoting co-benefits (e.g. in some cases for biodiversity
45 conservation through the endorsement of REDD+ initiatives and activities) and linkages to sustainable
46 development (e.g. through the Article 6.4 mechanism). Finally, in its preambular text the Paris
47 Agreement endorses both a human rights perspective and the concept of just transitions, creating
48 potential hooks for further elaboration and expansion of these principles in mitigation actions.

1 On the criterion of *economic performance*, the Paris Agreement’s performance is potentially enhanced
2 by the capacity for parties to link mitigation policies, therefore improving aggregate cost-effectiveness.
3 Voluntary cooperation under Article 6 of the Paris Agreement could facilitate such linkage of mitigation
4 policies (Chan et al. 2018). A combination of common accounting rules and the absence of restrictive
5 criteria and conditions on the use of ITMOs could accelerate linkage and increase the latitude of parties
6 to scale up the ambition of their NDCs. However, significant question marks remain over how the
7 environmental integrity of traded emissions reductions can be ensured (Mehling 2019). The ability of
8 Article 6 to contribute to the goal of the Paris Agreement will depend on the extent to which the rules
9 ensure environmental integrity and avoid double counting, while utilising the full potential of
10 cooperative efforts (Schneider et al. 2019; Michaelowa et al. 2019a).

11 In relation to the criterion of *institutional strength*, the Paris Agreement’s signalling and guidance
12 function is, however, arguably high. The Paris Agreement has the potential to interact with
13 complementary approaches to climate governance emerging beyond it (Held and Roger 2018). It may
14 also be used by publics – organised and mobilised in many countries and transnationally – as a point of
15 leverage in domestic politics to encourage countries to take costly mitigation actions (Keohane and
16 Oppenheimer 2016). More broadly, the Paris Agreement’s architecture provides flexibility for
17 decentralised forms of governance (Jordan et al. 2015; Victor 2016) (see further Section 14.5 below).
18 The Agreement has served a catalytic and facilitative role in enabling and facilitating climate action
19 from non-state and sub-state actors (Chan et al. 2015; Hale 2016; Chan et al. 2016; Bäckstrand et al.
20 2017; Kuyper et al. 2018b). Such action could potentially ‘bridge’ the ambition gap created by
21 insufficient NDCs from parties (Hsu et al. 2019b). The 2018 UNEP Emissions Gap Report estimates
22 that if ‘cooperative initiatives are scaled up to their fullest potential’, the impact of non-state and sub-
23 national actors could be up to 15-23 GtCO₂eq yr⁻¹ by 2030 compared to current policy, which could
24 bridge the gap (Lui et al. 2021). However, at present such a contribution is limited (Michaelowa and
25 Michaelowa 2017; UNEP 2018a). Non-state actors are also playing a role in enhancing the ambition of
26 individual NDCs by challenging their adequacy in national courts (see Chapter 13 and Section 14.5.3
27 below).

28 The Paris Agreement’s institutional strength in terms of ‘rules and standards to facilitate collective
29 action’ is disputed given the current lack of comparable information in NDCs (Peters et al. 2017; Pauw
30 et al. 2018; Mayer 2019; Zihua et al. 2019), and the extent to which its language, as well as that of the
31 Rulebook, strikes a balance in favour of discretion over prescriptiveness (Rajamani and Bodansky
32 2019). Similarly, in terms of ‘mechanisms to enhance transparency and accountability’, although
33 detailed rules relating to transparency have been developed under the Paris Rulebook, these rules permit
34 parties considerable self-determination in the extent and manner of application (Rajamani and
35 Bodansky 2019), and may not lead to further ambition (Weikmans et al. 2020). Further the Paris
36 Agreement’s compliance committee is facilitative and designed to ensure compliance with the
37 procedural obligations in the Agreement, rather than with the NDCs themselves, which are not subject
38 to obligations of result. The Paris Agreement does, however, seek to support the building of
39 transparency-related capacity of developing countries, potentially triggering institutional capacity-
40 building at the national, sub-national and sectoral level (see 14.3.2.7).

41 Ultimately, the overall effectiveness of the Paris Agreement depends on its ability to lead to ratcheting
42 up of collective climate action to meet the long-term global temperature goal (Bang et al. 2016; Christoff
43 2016; Young 2016; Dimitrov et al. 2019; Gupta and van Asselt 2019). As noted above, there is some
44 evidence that this is already occurring. The design of the Paris Agreement, with ‘nationally determined’
45 contributions at its centre, countenances an initial shortfall in collective ambition in relation to the long-
46 term global temperature goal on the understanding and expectation that Parties will enhance the
47 ambition of their NDCs over time (Article 4). This is essential given the current shortfall in ambition.
48 The pathways reflecting current NDCs, according to various estimates, imply global warming in the

1 range of 3°C by 2100 (UNFCCC 2016b; UNEP 2018a) (Chapter 4, Box 3). NDCs will need to be
2 substantially scaled up if the temperature goal of the Paris Agreement is to be met (Rogelj et al. 2018,
3 2016; Höhne et al. 2017, 2018; UNEP 2020). The Paris Agreement’s ‘ambition cycle’ is designed to
4 trigger such enhanced ambition over time. Some studies find that like-minded climate mitigation clubs
5 can deliver substantial emission reductions (Hovi et al. 2017) and are reasonably stable despite the
6 departure of a major emitter such as the United States (Sprinz et al. 2018), other studies find that
7 conditional commitments in the context of a pledge and review mechanism are unlikely to substantially
8 increase countries’ contributions to emissions reductions (Helland et al. 2017), and hence need to be
9 complemented by the adoption of instruments designed differently from the Paris Agreement (Barrett
10 and Dannenberg 2016). In any case, high (but not perfect) levels of mean compliance rates with the
11 Paris Agreement have to be assumed for reaching the ‘well below 2°C’ temperature goal (Sælen 2020;
12 Sælen et al. 2020). This is by no means assured.

13 In conclusion, it remains to be seen whether the Paris Agreement will deliver the collective ambition
14 necessary to meet the temperature goal. While the Paris Agreement does not contain strong and stringent
15 obligations of result for major emitters, backed by a demanding compliance system, it establishes
16 binding procedural obligations, lays out a range of normative expectations, and creates mechanisms for
17 regular review, stock taking, and revision of NDCs. In combination with complementary approaches to
18 climate governance, engagement of a wide range of non-state and sub-national actors, and domestic
19 enforcement mechanisms, these have the potential to deliver the necessary collective ambition and
20 implementation. Whether it will do so, remains to be seen.

21

22 **START CROSS-CHAPTER BOX 10 HERE**

23 **Cross-Chapter Box 10: Policy Attribution - Methodologies for estimating the macro-level** 24 **impact of mitigation policies on indices of GHG mitigation**

25 **Authors:** Mustafa Babiker (Saudi Arabia), Paolo Bertoldi (Italy), Christopher Bataille (Canada), Felix
26 Creutzig (Germany), Navroz K. Dubash (India), Michael Grubb (United Kingdom), Erik Haites
27 (Canada), Ben Hinder (United Kingdom), Janna Hoppe (Switzerland), Yong-Gun Kim (Republic of
28 Korea), Gregory Nemet (the United States of America), Anthony Patt (Switzerland), Yamina Saheb
29 (France), Raphael Slade (United Kingdom)

30 This report notes both a growing prevalence of mitigation policies over the past quarter century (Chapter
31 13), and ‘signs of progress’ including various quantified indices of GHG mitigation (Chapter 2, Table
32 2.4). Even though policies implemented and planned to date are clearly insufficient for meeting the
33 Paris long-term temperature goals, a natural question is to what extent the observed macro-level changes
34 (global, national, sectoral, technological) can be attributed to policy developments. This Assessment
35 Report is the first to address that question. This box describes the methods for conducting such
36 ‘attribution analysis’ as well as its key results, focusing on the extent to which policies have affected
37 three main types of ‘outcome indices’:

38 • **GHG emissions:** emissions volumes and trends at various levels of governance including sub- and
39 supra-national levels, and within and across sectors.

40 • **Proximate emission drivers:** trends in the factors that drive emissions, distinguished through
41 decomposition analyses, notably: energy/GDP intensity and carbon/energy intensity (for energy-related
42 emissions); indices of land use such as deforestation rates (for LULUCF/AFOLU); and more sector-
43 specific component drivers such as the floor area per capita, or passenger kilometres per capita.

44 • **Technologies:** developments in key low-carbon technologies that are likely to have a strong influence
45 on future emissions trends, notably levels of new investment and capacity expansions, as well as
46 technology costs, with a focus on those highlighted in Chapter 2 Figure 2.30.

1 *Policy attribution* examines the extent to which emission-relevant outcomes on these indices – charted
2 for countries, sectors and technologies, particularly in Chapter 2 and the sectoral chapters – may be
3 reasonably attributed to policies implemented prior to the observed changes. Such policies include
4 regulatory instruments such as energy efficiency programmes or technical standards and codes, carbon
5 pricing, financial support for low-carbon energy technologies and efficiency, voluntary agreements, and
6 regulation of land use practices. The sectoral chapters give more detail along with some accounts of
7 policy, whilst trends in mitigation policy adoption are summarised in Chapter 13.

8 In reviewing hundreds of scientific studies cited in this report, the impacts of adopted policies on
9 observed outcomes were assessed. The vast majority of these studies examine particular instruments in
10 particular contexts, as covered in the sectoral chapters and Chapter 13; only a few have appraised global
11 impacts of policies, directly or plausibly inferred (the most significant are cited in the figure in this
12 box). Typically, studies consider ‘mitigation policies’ to be those adopted with either a primary
13 objective of reducing GHG emissions or emissions reductions as one among multiple objectives.

14 Policies differ in design, scope, and stringency, may change over time as they require amendments or
15 new laws, and often partially overlap with other instruments. Overall, the literature indicates that policy
16 mixes are, theoretically and empirically, more effective in reducing emissions, stimulating innovation,
17 and inducing behavioural change than stand-alone policy instruments (Chapter 5 section 5.6; Chapter
18 13, section 13.7) (Rosenow et al. 2017; Sethi et al. 2020; Best and Burke 2018). Nevertheless, these
19 factors complicate analysis, because they give rise to the potential for double counting emissions
20 reductions that have been observed, and which separate studies can attribute to different policy
21 instruments.

22 Efforts to attribute observed outcomes to a policy or policy mix is also greatly complicated by the
23 influence of many exogenous factors, including fossil fuel prices and socio-economic conditions.
24 Likewise, technological progress can result from both exogenous causes, such as ‘spillover’ from other
25 sectors, and policy pressure. Further, other policies, such as fossil fuel subsidies as well as trade-related
26 policies, can partially counteract the effect of mitigation policies by increasing the demand for energy
27 or carbon-intensive goods and services. In some cases, policies aimed at development, energy security,
28 or air quality have climate co-benefits, while others increase emissions.

29 Studies have applied a number of methods to identify the actual effects of mitigation policies in the
30 presence of such confounding factors. These include statistical attribution methodologies, including
31 experimental and quasi-experimental design, instrumental variable approaches, and simple correlational
32 methods. Typically, the relevant mitigation metric is the outcome variable, while measures of policies
33 and other factors act as explanatory variables. Other methodologies include aggregations and
34 extrapolations from micro-level data evaluation, and inference from combining multiple lines of
35 analysis, including expert opinion. Additionally, the literature contains reviews, many of them
36 systematic in nature, that assess and aggregate multiple empirical studies.

37 With these considerations in mind, multiple lines of evidence, based upon the literature, support a set
38 of high-level findings, as illustrated in the figure in this box, as follows.

39 **1. GHG Emissions.** There is robust evidence with a high level of agreement that mitigation policies
40 have had a discernible impact on emissions. Several lines of evidence indicate that mitigation policies
41 have led to avoided global emissions to date by several billion tonnes CO₂-eq annually. The figure in
42 this box shows a selection of results giving rise to this estimate.

43 As a starting point, one methodologically sophisticated econometric study links global mitigation
44 policies (defined as climate laws and executive orders) to emission outcomes; it estimates emission
45 savings of 5.9 GtCO₂ yr⁻¹ in 2016 compared to a no-policy world (Eskander and Fankhauser 2020, see
46 Chapter 13.6.2).

1 A second line of evidence derives from analyses of the Kyoto Protocol. Countries which took on Kyoto
2 Protocol targets accounted for about 24% of global emissions during the first commitment period (2008-
3 12). The most recent robust econometric assessment (Maamoun 2019) estimates that these countries cut
4 GHG emissions by about 7% on average over 2005-2012, rising over the period to around 12% (1.3
5 GtCO_{2e} yr⁻¹) *relative to a no-Kyoto scenario*. This is consistent with estimates of Grunewald and
6 Martinez (2016) of about 800 MtCO_{2e} yr⁻¹ averaged to 2009. Developing countries emission reduction
7 projects through the CDM (defined in article 12 of the Kyoto Protocol) were certified as growing to
8 over 240 MtCO_{2e} yr⁻¹ by 2012 (UNFCCC 2021c). With debates about the full extent of ‘additionality’,
9 academic assessments of savings from the CDM have been slightly lower with particular concerns
10 around some non-energy projects (see Chapter 14.3.3.1).

11 A third line of evidence derives from studies that identify policy-related, absolute reductions from
12 historical levels in particular countries and sectors through decomposition analyses (e.g., Lamb et al.
13 2021; Le Quéré et al. 2019), or evaluate the impact of particular policies, such as carbon pricing systems.
14 From a wide range of estimates in the literature (see Chapters 2.8.2.2 and 13.6), many evaluations of
15 the EU ETS suggest that it has reduced emissions by around 3% to 9% relative to unregulated firms
16 and/or sectors (Schäfer 2019; Colmer et al. 2020), whilst other factors, both policy (energy efficiency
17 and renewable support) and exogenous trends, played a larger role in the overall reductions seen (Haites
18 2018).

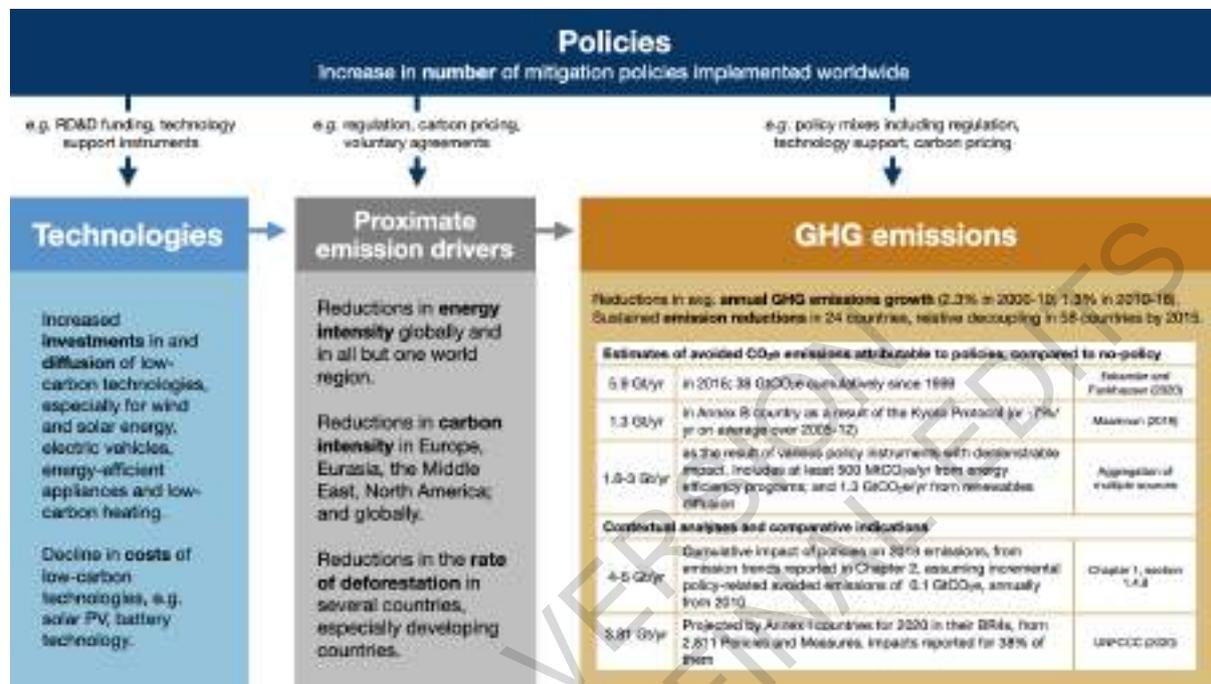

19 These findings derived from the peer-reviewed literature are also consistent with two additional sets of
20 analysis. The first set concerns trends in emissions, drawing directly from Chapters 6-11 and Chapter
21 2, showing that global annual emission growth has slowed as evidenced by annual emission increments
22 of 0.55 GtCO_{2e} yr⁻¹ between 2011 and 2019 compared to 1.014 GtCO_{2e} yr⁻¹ in 2000-08. This suggests
23 avoided emissions of 4-5 Gt yr⁻¹ (see also Chapter 1, Figure 1.1d). The second set concerns emissions
24 reductions projected by Annex I governments for 2020 in their fourth biennial reports to the UNFCCC.
25 It is important to note that these are mostly projected annual savings from implemented policies (not
26 *ex-post* evaluations), and there are considerable differences in countries’ estimation methodologies.
27 Nevertheless, combining estimates from 38% of the total of 2,811 reported policies and measures yields
28 an overall estimate of 3.81GtCO_{2e} yr⁻¹ emission savings (UNFCCC 2020d).

29 **2. Proximate emission drivers.** With less overt focus on emissions, studies of trends in energy
30 efficiency, carbon intensity, or deforestation often point to associated policies. The literature s includes
31 an increasing number of studies on demonstrable progress in developing countries. For example, South
32 and South-East Asia have seen energy intensity in buildings improving at ca. 5 – 6% yr⁻¹ since 2010
33 (Chapter 2, Figure 2.22). In India alone, innovative programmes in efficient air conditioning, LED
34 lighting, and industrial efficiency are reported as saving around 25 Mtoe in 2019-2020, thus leading to
35 avoided emissions of over 150 MtCO₂ yr⁻¹ (see Chapter 16, box 16.3; Malhotra et al. 2021). Likewise,
36 reductions in deforestation rates in several South and Central American and Asian countries are at least
37 partly attributable to ecosystem payments, land use regulation, and internal efforts (Chapter 7.6.2).
38 Finally, the policy-driven displacement of fossil fuel combustion by renewables in energy has led to
39 reductions in carbon intensity in several world regions (Chapters 2 and 6).

40 **3. Technologies.** The literature indicates unambiguously that the rapid expansion of low-carbon energy
41 technologies is substantially attributable to policy (Chapter 6.7.5, Chapter 16.5). Technology-specific
42 adoption incentives have led to a greater use of less carbon-intensive (e.g. renewable electricity) and
43 less energy-intensive (especially in transport and buildings) technologies. As Chapters 2 and 6 of this
44 report note, modern renewable energy sources currently satisfy over 9% of global electricity demand,
45 and this is largely attributable to policy. There are no global-level studies estimating the avoided
46 emissions due to renewable energy support policies, but there are methods that have been developed to
47 link renewable energy penetration to avoided emissions, such as that of IRENA (2021). Using that
48 method, and assuming that 70% of modern renewable energy expansion has been policy-induced, yields

1 an estimate of avoided emissions of 1.3 GtCO₂e yr⁻¹ in 2019. Furthermore, observed cost reductions
 2 are the result of policy-driven capacity expansion as well as publicly funded R&D, in individual
 3 countries and globally. These correspond with induced effects on number of patents, ‘learning curve’
 4 correlations with deployed capacity, and cost component and related case study analyses (Kavlak et al.
 5 2018; Nemet 2019; Popp 2019; Grubb et al. 2021).

13

14 **14.4 Supplementary means and mechanisms of implementation**

15 As discussed above, the Paris Agreement sets in place a new framework for international climate policy
 16 albeit one that is embedded in the wider climate regime complex (Coen et al. 2020). Whereas
 17 international governance had earlier assumed centre stage, the Paris Agreement recognises the salience
 18 of domestic politics in the governance of climate change (Kinley et al. 2020). The new architecture also
 19 provides more flexibility for recognising the benefits of working in diverse forms and groups and allows
 20 for more decentralised “polycentric” forms of governance (Jordan et al. 2015; Victor 2016). The next
 21 two sections address this complementarity between the Paris Agreement and other agreements and
 institutions.

22 The Paris Agreement identifies a number of pathways, or means of implementation, towards
 23 accomplishing rapid mitigation and the achieving of its temperature goal: finance; capacity building;
 24 technology and innovation; and, cooperative approaches and markets (see sections 14.3.2.7-14.3.2.10
 25 above). In this section, we examine each of these means and mechanisms of implementation, and the
 26 agreements and institutions lying outside of the Paris Agreement that contribute to each. In the
 27 following Section, 14.5, we examine the agreements and institutions playing other governance roles:
 28 regulating activities in particular sectors; linking climate mitigation with other activities such as
 29 adaptation; and, stimulating and coordinating the actions of non-state actors at a global scale.

1 Figure 14.3 maps out the interlinkages described in the text of the sections 14.4 and 14.5. It is an
 2 incomplete list, but illustrates clearly that across multiple types of governance, there are multiple
 3 instruments or organisations with activities connected to the different governance roles associated with
 4 the Paris Agreement and the UNFCCC more generally.

Type	Instrument / Organization	Mitigation	Transparency	Sinks	Markets	Finance	Technology	Capacity building
Global treaties	Montreal Protocol	14.5.1.1				14.5.1.1

 8 **UNFCCC and Paris Agreement.**

9 14.4.1 Finance

10 International cooperation on climate finance is underpinned by various articles of the UNFCCC
 11 including Articles 4.3, 4.4, 4.5, 4.7 and 11.5 (UNFCCC 1992). This was further amplified through the
 12 commitment by developed countries in the Copenhagen Accord and the Cancun Agreements to mobilise
 13 jointly through various sources USD100 billion yr⁻¹ by 2020 to meet the needs of the developing
 14 countries (UNFCCC 2010b). This commitment was made in the context of meaningful mitigation action
 15 and transparency of implementation. As mentioned earlier in Section 14.3.2.8, in the Paris Agreement
 16 the binding obligation on developed country parties to provide financial resources to assist developing
 17 country parties applies to both mitigation and adaptation (UNFCCC 2015a, Art. 9.1). In 2019, climate
 18 finance provided and mobilised by developed countries was in the order of USD79.6 billion, coming
 19 from different channels including bilateral and multilateral channels, and also through mobilisation of
 20 the private sector attributable to these channels (OECD 2021). A majority (two-thirds) of these flows
 21 targeted mitigation action exclusively (see also Chapter 15). These estimates, however, have been
 22 criticised on various grounds, including that they are an overestimate and do not represent climate
 23 specific net assistance only; that in grant equivalence terms the order of magnitude is lower; and the
 24 questionable extent of transparency of information on mobilised private finance, as well as the direction
 25 of these flows (Carty et al. 2020). On balance, such assessments need to be viewed in the context of the
 26 original commitment, the source of the data and the evolving guidance, and modalities and procedures
 27 from the UNFCCC processes. As mentioned in Chapter 15, the measurement of climate finance flows
 28 continues to face definitional, coverage and reliability issues despite progress made by various data
 29 providers and collators (see section 15.3.2 in Chapter 15).

1 The multiplicity of actors providing financial support has resulted in a fragmented international climate
2 finance architecture as indicated in Section 14.3.2.8. It is also seen as a system which allows for speed,
3 flexibility and innovation (Pickering et al. 2017). However, the system is not yet delivering adequate
4 flows given the needs of developing countries (see Section 14.3.2.8). An early indication of these self-
5 assessed needs is provided in the conditional NDCs. Of the 136 conditional NDCs submitted by June
6 2019, 110 have components or additional actions conditioned on financing support for mitigation and
7 79 have components or additional actions for support for adaptation (Pauw et al. 2020). While the Paris
8 Agreement did not explicitly countenance conditionality for actions in developing countries, it is
9 generally understood that the ambition and effectiveness of climate ambition in these countries is
10 dependent on financial support (Voigt and Ferreira 2016b).

11 **14.4.1.1 Bilateral finance**

12 The Paris Agreement and the imperative for sustainable development reinforce the need to forge strong
13 linkages between climate and development (Fay et al. 2015). This in turn has highlighted the urgent
14 need for greater attention to the relationship between development assistance and finance, and climate
15 change (Steele 2015).

16 The UNFCCC website cites some 20 bilateral development agencies providing support to climate
17 change programs in developing countries (UNFCCC 2020a). These agencies provide a mix of
18 development cooperation, policy advice and support and financing for climate change projects. Since
19 the year 2000, the OECD Development Assistance Committee has been tracking trends in climate-
20 related development finance and assistance. The amount of bilateral development finance with climate
21 relevance has increased substantially since 2000 (OECD 2019a). For 2019, it was reported to be
22 USD28.8 billion in direct finance and USD2.6 billion through export credit agencies. Further, another
23 USD34.1 billion of the climate finance provided through multilateral channels is attributable to the
24 developed countries (OECD 2021). The OECD methodology has been critiqued as it uses Rio markers
25 the limitations of which could lead to erroneous reporting and assessment of finance provided as well
26 as the mitigation outcome (Michaelowa and Michaelowa 2011b; Weikmans and Roberts 2019). This
27 issue is to be addressed through the modalities, procedures and guidance under the Enhanced
28 Transparency Framework of the Paris Agreement (see Section 14.3.2.4), through the mandate to
29 Subsidiary Body for Scientific and Technological Advice (SBSTA) to develop Common Tabular
30 Formats (CTFs) for the reporting of information on, *inter alia*, financial support provided, mobilised
31 and received (UNFCCC 2019k). Until then, the Biennial Assessment Report prepared by the Standing
32 Committee on Finance provides the best available information on financial support.

33 **14.4.1.2 Multilateral finance**

34 Multilateral Development Banks (MDBs) comprise six global development banks that include the
35 European Investment Bank (EIB), International Fund for Agricultural Development (IFAD),
36 International Investment Bank (IIB), New Development Bank (NDB), OPEC Fund for International
37 Development (OFID), and the World Bank Group, six regional development banks that include the
38 African Development Bank (AfDB), Asian Development Bank (AsDB), Asian Infrastructure
39 Investment Bank (AIIB), European Bank for Reconstruction and Development (EBRD), Inter-
40 American Development Bank (IADB), and the Islamic Development Bank (IsDB), and thirteen sub-
41 regional development banks that include the Arab Bank for Economic Development in Africa
42 (BADEA), Arab Fund for Economic and Social Development (AFESD), Black Sea Trade and
43 Development Bank (BSTDB), Caribbean Development Bank (CDB), Central American Bank for
44 Economic Integration (CABEI), Development Bank of the Central African States (BDEAC),
45 Development Bank of Latin America (CAF), East African Development Bank (EADB), Eastern and
46 Southern African Trade and Development Bank (TDB), Economic Cooperation Organization Trade and
47 Development Bank (ETDB), ECOWAS Bank for Investment and Development (EBID), Eurasian
48 Development Bank (EDB), and the West African Development Bank (BOAD). Together they play a key

1 role in international cooperation at the global, regional and sub-regional level because of their growing
2 mandates and proximity to policymakers (Engen and Prizzon 2018). For many, climate change is a
3 growing priority and for some, because of the needs of the regions, or sub-regions in which they operate,
4 climate change is embedded in many of their operations.

5 In 2015, twenty representative MDBs and members of the International Development Finance Club
6 unveiled five voluntary principles to mainstream climate action in their investments, including
7 commitment to climate strategies, managing climate risks, promoting climate smart objectives,
8 improving climate performance and accounting for their own actions (World Bank 2015a; Institute for
9 Climate Economics 2017). The members subscribing to these principles have since grown to 44 in
10 January 2020. Arguably, it is only through closer linkages between climate and development that
11 significant inroads can be made in addressing climate change. MDBs can play a major role through the
12 totality of their portfolios (Larsen et al. 2018).

13 The MDBs as a cohort have been collaborating and coordinating in reporting on climate financing since
14 2012 following a commitment made in 2012 at the Rio +20 summit (MDB 2012). This has engendered
15 other forms of collaboration among the MDBs, including: commitments to collectively total at least
16 USD65 billion annually by 2025 in climate finance, with USD50 billion for low and middle income
17 economies; to mobilise a further USD40 billion annually by 2025 from private sector investors,
18 including through the increased provision of technical assistance, use of guarantees, and other de-
19 risking instruments; and to commit to helping clients deliver on the goals of the Paris Agreement;
20 building a transparency framework on impact of MDBs' activities and enabling clients to move away
21 from fossil fuels (Asian Development Bank 2019). While the share of MDBs in direct climate financing
22 is small, their role in influencing national development banks and local financial institutions, and
23 leveraging and crowding in private investments in financing sustainable infrastructure, is widely
24 recognised (NCE 2016). However, with this recognition there is also an exhortation to do more to align
25 with the goals of the Paris Agreement, including a comprehensive examination of their portfolios
26 beyond investments that directly support climate action to also enabling the long-term net zero GHG
27 emissions trajectory (Cochran and Pauthier 2019; Larsen et al. 2018). Further, a recent assessment has
28 shown that MDBs perform relatively better in mobilising other public finance than private co- financing
29 (Thwaites 2020). In addition, the banks have launched or are members of significant initiatives such as
30 the Climate and Clean Air Coalition (CCAC) to reduce short lived climate pollutants, the Carbon
31 Pricing Leadership Coalition (CPLC), the Coalition for Climate Resilient Investment (CCRI) and the
32 Coalition of Finance Ministers for climate action. These help to spur action at different levels, from
33 economic analysis, to carbon financing and convenors of finance and development ministers for climate
34 action, with leadership of many of these initiatives led by the World Bank.

35 The multilateral climate funds also have a role in the international climate finance architecture. This
36 includes, as mentioned in Section 14.3.2.8, those established under the UNFCCC's financial
37 mechanism, its operating entities, the Global Environment Facility (GEF), which also manages two
38 special funds, the Special Climate Change Fund (SCCF) and the Least Developed Countries Fund
39 (LDCF); the Green Climate Fund (GCF), also an operating entity of the financial mechanism which in
40 2015, was given a special role in supporting the Paris Agreement. The GCF aims to provide funding at
41 scale, balanced between mitigation and adaptation, using various financial instruments including grants,
42 loans, equity, guarantees or others to activities that are aligned with the priorities of the countries
43 compatible with the principle of country ownership (GCF 2011). The GCF faces many challenges.
44 While some see the GCF as an opportunity to transform and rationalise what is now a complex and
45 fragmented climate finance architecture with insufficient resources and overlapping remits (Nakhoda
46 et al. 2014), others see it as an opportunity to address the frequent tensions which arise between
47 mitigation-focused transformation and national priorities of countries. This tension is at the heart of the
48 principle of country ownership and the need for transformational change (Winkler and Dubash 2016).

1 Leveraging private funds and investments by the public sector, taking risks to unlock climate action are
2 also expressed strategic aims of the GCF.

3 The UN system is also supporting climate action through much needed technical assistance and capacity
4 building, which is complementary to the financial flows insofar as it enables countries with relevant
5 tools and methodologies to assess their needs, develop national climate finance roadmaps, establish
6 relevant institutional mechanisms to receive support and track it, enhance readiness to access financing,
7 and include climate action across relevant national financial planning and budgeting processes (UN
8 2017a). The United Nations Development Programme (UNDP) is the largest implementer of climate
9 action among the UN Agencies, with others, such as the Food and Agriculture Organisation (FAO),
10 United Nations Environment Programme (UNEP), United Nations Industrial Development
11 Organisation (UNIDO), and United Nations Office for South-South Cooperation (UNOSSC), providing
12 relevant support.

13 The current architecture of climate finance is one that is primarily based on north-south, developed-
14 developing country dichotomies. The Paris Agreement, however, has clearly recognised the role of
15 climate finance flows across developing countries, thereby enhancing the scope of international
16 cooperation (Voigt and Ferreira 2016b). Estimates of such flows, though, are not readily available.
17 According to one estimate in 2020 the flows among non-OECD countries were of the order of USD29
18 billion (CPI 2021).

19 **14.4.1.3 Private sector financing**

20 There is a growing recognition of the importance of mobilising private sector financing including for
21 climate action (World Bank 2015b; Michaelowa et al. 2020b). An early example of the mobilisation of
22 the private sector in a cooperative mode for mitigation outcomes is evidenced from the Clean
23 Development Mechanism of the Kyoto Protocol and the linking with the European Union's Emissions
24 Trading Scheme, both triggered by relevant provisions in the Kyoto Protocol (see Section 14.4.4) and
25 lessons learnt from this are relevant for development of market mechanisms in the post Paris Agreement
26 period (Michaelowa et al. 2019b). In 2019/2020, on an average for the two years, public and private
27 climate financing was on the order of USD632 billion, of which USD310 billion originated from the
28 private sector. However, as much as 76% of the (overall) finance stayed in the country of origin. This
29 trends holds true also for private finance (CPI 2021). Figure 14.4 depicts the international climate
30 finance flows totalling USD161 billion reported in 2020, about 19% were private flows. For
31 (international) mitigation financing flows of USD116 billion, the share provided by private sources was
32 24%.

33

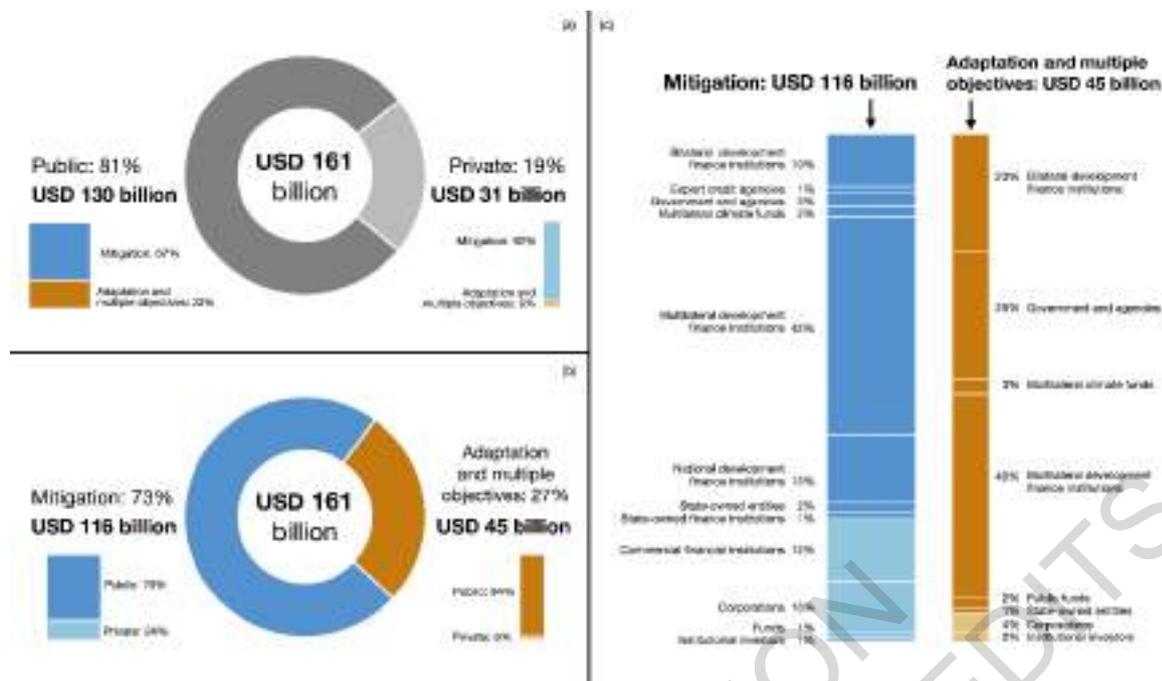

Figure 14.4 International Finance Flows. Total international climate financial flows for 2020 were USD161 billion. By comparison, public sector bilateral and multilateral finance in 2017 for fossil fuel development, including gas pipelines, was roughly USD4 billion. Part (a) disaggregates total financial flows according to public and private sources, and indicates the breakdown between mitigation on the one hand, and adaptation and multiple objectives on the other, within each source. Part (b) disaggregates total financial flows according to intended purpose, namely mitigation or adaptation and multiple objectives, and disaggregates each type according to source. Part (c) provides additional detail on the relative contributions of different public and private sources. Sources: (CPI 2021; OECD 2021).

Foreign direct investments and its greening is seen as a channel for increasing cooperation. An assessment of the greenfield foreign direct investment in different sectors shows the growing share of renewable energy at USD92.2 billion (12% of the volume and 38% of the number of projects) (FDI Intelligence 2020). Coal, oil and gas sectors maintain the top spot for capital investments globally. Over the last decade there is growing issuance of green bonds with non-financial private sector issuance gaining ground (Almeida 2020). While it is questionable if green bonds have a significant impact on shifting capital from non-sustainable to sustainable investments, they do incentivise the issuing organisations to enhance their green ambition and have led to an appreciation within capital markets of green frameworks and guidelines and signalling new expectations (Maltais and Nykvist 2020). In parallel, institutional investors including pension funds are seeking investments that align with the Paris Agreement (IIGCC 2020). However, the readiness of institutional investors to make this transition is arguable (OECD 2019b; Ameli et al. 2020). This evidence suggests that international private financing could play an important role but this potential is yet to be realised (see Chapter 15).

14.4.2 Science, technology and innovation

Science, technology and innovation are essential for the design of effective measures to address climate change and, more generally, for economic and social development (de Coninck and Sagar 2015a). The OECD finds that single countries alone often cannot provide effective solutions to today's global challenges, as these cross national borders and affect different actors (OECD 2012). Madani (2020) shows how conflict, including international sanctions, can reduce science and innovation capacity,

1 which is not evenly distributed, particularly across the developed and the developing world. For this
2 reason, many countries have introduced strategies and policies to enhance international cooperation in
3 science and technology (Chen et al. 2019). Partnerships and international cooperation can play a role in
4 establishing domestic innovation systems, which enable more effective science and technology
5 innovation (de Coninck and Sagar 2015b,a).

6 International cooperation in science and technology occurs across different levels, with a growing
7 number of international cooperation initiatives aimed at research and collaborative action in technology
8 development. (Weart 2012) finds that such global efforts are effective in advancing climate change
9 science due to the international nature of the challenge. Global research programmes and institutions
10 have also provided the scientific basis for major international environmental treaties. For example, the
11 Long-Range Transboundary Air Pollution Convention and the Montreal Protocol were both informed
12 by scientific assessments based on collaboration and cooperation of scientists across several
13 geographies (Andresen et al. 2000). Furthermore, the Global Energy Assessment (GEA 2012) provided
14 the scientific basis and evidence for the 2030 Agenda for Sustainable Development, in particular SDG7
15 to ensure access to affordable, reliable and sustainable modern energy for all. The GEA drew on the
16 expertise of scientists from over 60 countries and institutions. Several other platforms exist to provide
17 scientists and policymakers an opportunity for joint research and knowledge sharing, such as The World
18 in 2050, an initiative that brings together scientists from some 40 institutions from around the world to
19 provide the science for SDG and Paris Agreement implementation (TWI2050 2018).

20 Non-state actors are also increasingly collaborating internationally. Such collaborations, referred to as
21 international cooperative initiatives (ICIs), bring together multi-stakeholder groups across industry,
22 communities, and regions, and operate both within and outside the UNFCCC process. Lui et al. (2021)
23 find that such initiatives could make a major contribution to global emissions reduction, Bakhtiari
24 (2018) finds that the impact on greenhouse gas reduction of these initiatives is hindered due to a lack
25 of coordination between ICIs, overlap with other activities conducted by the UNFCCC and
26 governments, and a lack of monitoring system to measure impact. Increasing the exchange of
27 information between ICIs, enhancing monitoring systems, and increasing collaborative research in
28 science and technology would help address these issues (Boekholt et al. 2009; Bakhtiari 2018).

29 At the level of research institutes, there has been a major shift to a more structured and global type of
30 cooperation in research; Wagner et al. (2017) found significant increases in both the proportion of
31 papers written by author teams from multiple countries, and in the number of countries participating in
32 such collaboration, over the time period 1990 - 2013. Although only a portion of these scientific papers
33 address the issue of climate change specifically, this growth of scientific collaboration across borders
34 provides a comprehensive view of the conducive environment in which climate science collaboration
35 has grown.

36 However, there are areas in which international cooperation can be strengthened. Both the Paris
37 Agreement and the 2030 Agenda for Sustainable Development call for more creative forms of
38 international cooperation in science that help bridge the science and policy interface, and provide
39 learning processes and places to deliberate on possible policy pathways across disciplines on a more
40 sustainable and long-lasting basis. Scientific assessments, such as the IPCC and IPBES offer this
41 possibility, but processes need to be enriched for this to happen more effectively (Kowarsch et al. 2016)

42 A particular locus for international cooperation on technology development and innovation is found
43 within institutions and mechanisms of the UN climate regime. The UNFCCC, in Article 4.1(c), calls on
44 'all parties' to 'promote and cooperate in the development, application and diffusion, including transfer,
45 of technologies, practices and processes that control, reduce or prevent anthropogenic emissions of
46 greenhouse gases' and places responsibility on developed country parties to 'take all practicable steps
47 to promote, facilitate and finance, as appropriate, the transfer of, or access to environmentally sound
48 technologies and know-how to other parties, particularly developing country parties, to enable them to

1 implement the provisions of the Convention’ (UNFCCC 1992, Art. 4.5). The issue of technology
2 development and transfer has continued to receive much attention in the international climate policy
3 domain since its initial inclusion in the UNFCCC in 1992 – albeit often overshadowed by dominant
4 discourses around market-based mechanisms – and its role in reducing GHG emissions and adapting to
5 the consequences of climate change ‘is seen as becoming ever more critical’ (de Coninck and Sagar
6 2015a). Milestones in the development of international cooperation on climate technologies under the
7 UNFCCC have included: (1) the development of a technology transfer framework and establishment of
8 the Expert Group on Technology Transfer (EGTT) under the Subsidiary Body for Scientific and
9 Technological Advice (SBSTA) in 2001; (2) recommendations for enhancing the technology transfer
10 framework put forward at the Bali Conference of the Parties in 2007 and creation of the Poznan strategic
11 program on technology transfer under the Global Environmental Facility (GEF); and (3) the
12 establishment of the Technology Mechanism by the Conference of the Parties in 2010 as part of the
13 Cancun Agreements (UNFCCC 2010b). The Technology Mechanism is presently the principal avenue
14 within the UNFCCC for facilitating cooperation on the development and transfer of climate
15 technologies to developing countries (UNFCCC 2015b). As discussed in Section 14.3.2.9 above, the
16 Paris Agreement tasks the Technology Mechanism also to serve the Paris Agreement (UNFCCC 2015b,
17 Art. 10.3).

18 The Technology Mechanism consists of the Technology Executive Committee (TEC) (replacing the
19 EGTT), as its policy arm, and the Climate Technology Centre and Network (CTCN), as its
20 implementation arm (UNFCCC 2015b). The TEC focuses on identifying and recommending policies
21 that can support countries in enhancing and accelerating the development and transfer of climate
22 technologies (UNFCCC 2020b). The CTCN facilitates the transfer of technologies through three core
23 services: (1) providing technical assistance at the request of developing countries; (2) creating access
24 to information and knowledge on climate technologies; and (3) fostering collaboration and capacity-
25 building (CTCN 2020a). The CTCN ‘network’ consists of a diverse set of climate technology
26 stakeholders from academic, finance, non-government, private sector, public sector, and research
27 entities, together with more than 150 National Designated Entities, which serve as CTCN national focal
28 points. Through its network, the CTCN seeks to mobilise policy and technical expertise to deliver
29 technology solutions, capacity-building and implementation advice to developing countries (CTCN
30 2020b). At the Katowice UNFCCC Conference of the Parties in 2018, the TEC and CTCN were
31 requested to incorporate the technology framework developed pursuant to Article 10 of the Paris
32 Agreement into their respective workplans and programmes of work (UNFCCC 2019f).

33 The Joint Annual Report of the TEC and CTCN for 2019 indicated that, as of July 2019, the CTCN had
34 engaged with 93 developing country parties regarding a total of 273 requests for technical assistance,
35 including 11 multi-country requests. Nearly three-quarters (72.9%) of requests received by the CTCN
36 had a mitigation component, with two-thirds of those mitigation requests related to either renewable
37 energy or energy efficiency. Requests for decision-making or information tools are received most
38 frequently (28% of requests), followed by requests for technology feasibility studies (20%) and
39 technology identification and prioritisation (18%) (TEC and CTCN 2019).

40 The CTCN is presently funded from ‘various sources, ranging from the [UNFCCC] Financial
41 Mechanism to philanthropic and private sector sources, as well as by financial and in-kind contributions
42 from the co-hosts of the CTCN and from participants in the Network’ (TEC and CTCN 2019, para. 97).
43 Oh (2020b) describes the institution as ‘mainly financially dependent on bilateral donations from
44 developed countries and multilateral support’. Nevertheless, inadequate funding of the CTCN poses a
45 problem for its effectiveness and capacity to contribute to implementation of the Paris Agreement. A
46 2017 independent review of the CTCN identified ‘limited availability of funding’ as a key constraint
47 on its ability to deliver services at the expected level and recommended that ‘[b]etter predictability and
48 security over financial resources will ensure that the CTCN can continue to successfully respond to its

1 COP mandate and the needs and expectations of developing countries' (Ernst & Young 2017, para. 84).
2 The 2019 Joint Report of the TEC and CTCN indicates that resource mobilisation for the Network
3 remains a challenge (TEC and CTCN 2019, pp. 23-24).

4 The importance of 'financial support' for strengthening cooperative action on technology development
5 and transfer was recognised in Article 10.6 of the Paris Agreement. The technology framework
6 established by the Paris Rulebook specifies actions and activities relating to the thematic area of
7 'support' as including: (a) enhancing the collaboration of the Technology Mechanism with the Financial
8 Mechanism; (b) identifying and promoting innovative finance and investment at different stages of the
9 technology cycle; (c) providing enhanced technical support to developing country parties, in a country-
10 driven manner, and facilitating their access to financing for innovation, enabling environments and
11 capacity-building, developing and implementing the results of TNAs, and engagement and
12 collaboration with stakeholders, including organisational and institutional support; and (d) enhancing
13 the mobilisation of various types of support, including pro bono and in-kind support, from various
14 sources for the implementation of actions and activities under each key theme of the technology
15 framework.

16 Notwithstanding the technology framework's directive for enhanced collaboration of the Technology
17 and Financial Mechanisms of the UNFCCC, linkages between them, and particularly to the GCF,
18 continue to engender political contestation between developing and developed countries (Oh 2020b).
19 Developing countries sought to address concerns over the unsustainable funding status of the CTCN by
20 advocating linkage through a funding arrangement or financial linkage, whereas developed countries
21 favour the design of an institutional linkage maintaining the different and separate mandates of the
22 CTCN and the GCF (Oh 2020a,b). With no resolution reached, the UNFCCC COP requested the
23 Subsidiary Body for Implementation, at its fifty-third session, to take stock of progress in strengthening
24 the linkages between the Technology Mechanism and the Financial Mechanism with a view to
25 recommending a draft decision for consideration and adoption by the Glasgow COP, scheduled for 2021
26 (UNFCCC 2019).

28 **14.4.3 Capacity Building**

29 International climate cooperation has long focused on supporting developing countries in building
30 capacity to implement climate mitigation actions. While there is no universally agreed definition of
31 capacity-building and the UNFCCC does not define the term (Khan et al. 2020), elements of capacity-
32 building can be discerned from the Convention's provisions on education and training programmes
33 (UNFCCC 1992, Art. 6), as well as the reference in Article 9(2)(d) of the UNFCCC to the Subsidiary
34 Body for Scientific and Technological Advice (SBSTA) providing support for 'endogenous capacity-
35 building in developing countries.'

36 Capacity-building is generally conceived as taking place at three levels: individual (focused on
37 knowledge, skills and training), organisational/institutional (focusing on organisational performance
38 and institutional cooperation) and systemic (creating enabling environments through regulatory and
39 economic policies (Khan et al. 2020; UNFCCC 2021b). In its annual synthesis report for 2018, the
40 UNFCCC secretariat compiled information submitted by parties on the implementation of capacity-
41 building in developing countries, highlighting cooperative and regional activities on NDCs, including
42 projects to build capacity for implementation, workshops related to transparency under the Paris
43 Agreement and collaboration to provide coaching and training (UNFCCC 2019h). A number of
44 developing country Parties also highlighted their contributions to South-South cooperation (discussed
45 further in Section 14.5.1.4 below), and identified capacity-building projects undertaken with others (e.g.
46 capacity-building for risk management in Latin America and the Caribbean, improving capacity for

1 measurement, reporting and verification (MRV) through the Alliance of the Pacific and a climate action
2 package launched by Singapore).

3 Beyond the UNFCCC, other climate cooperation and partnership activities on capacity building include
4 climate-related bilateral cooperation and those organised by the OECD, IFDD (Francophonie Institute
5 for Sustainable Development), UNDP-NCSP programme, UNEP and the World Bank.

6 Climate-related bilateral cooperation provides important human and institutional capacity building
7 supports for climate change actions and activities in developing countries, particularly through
8 developed countries' bilateral cooperation structures, such as the French Development Agency (AFD),
9 the German Development Agency (The Deutsche Gesellschaft für Internationale Zusammenarbeit –
10 GIZ), the Japanese International Cooperation Agency (JICA) and others.

11 There are also a number of regional cooperative structures with capacity-building components,
12 including ClimaSouth, Euroclima+, the UN-REDD Programme, the Caribbean Regional Strategic
13 Programme for Resilience, the Caribbean Climate Online Risk and Adaptation Tool, a project on
14 accelerating low carbon and resilient society realisation in the Southeast Asian region, the World Health
15 Organisation's Global Salm-Surv network, the Red Iberoamericana de Oficinas de Cambio Climático
16 network and the Africa Adaptation Initiative. Many climate-related capacity-building initiatives,
17 including those coordinated or funded by international or regional institutions, are implemented at the
18 national and sub-national level, often with the involvement of universities, consultancy groups and civil
19 society actors.

20 It is also noted that comprehensive support is provided by the GCF to developing countries (GCF,
21 2020). This support is made available and accessible for all developing countries through three different
22 GCF tools: the Readiness Programme, the Project Preparation Facility, and the funding of
23 transformative projects and programmes. The goal of the Readiness Programme is to strengthen
24 institutional capacities, governance mechanisms, and planning and programming competencies in
25 support of developing countries' transformational long-term climate policies (GCF, 2020). Despite a
26 decades-long process of capacity-building efforts under many development and environmental regimes,
27 including the UNFCCC, progress has been uneven and largely unsuccessful in establishing institution-
28 based capacity in developing countries (Robinson 2018). In an effort to improve capacity-building
29 efforts within the UNFCCC, in 2015, the Paris Committee on Capacity-building (PCCB) was
30 established by the COP decision accompanying the Paris Agreement as the primary body for enhancing
31 capacity-building efforts, including by improving coherence and coordination in capacity-building
32 activities (UNFCCC 2016a, para. 71). The activities of the Committee include the provision of guidance
33 and technical support on climate change training and capacity building, raising awareness and sharing
34 climate information and knowledge. During 2020, the PCCB was able, despite the Covid-19 situation,
35 to hold its 4th meeting, implement and assess its 2017-2020 work plan, and develop and agree on its
36 future roadmap (2021-2024) (UNFCCC Subsidiary Body for Implementation 2020). Non-governmental
37 organisations such as the Coalition on Paris Agreement Capacity-building provide expert input to the
38 PCCB.

39 Quantifying the contribution of capacity-building efforts to climate mitigation is acknowledged to be
40 'difficult, if not impossible' (Hsu et al. 2019a). Nonetheless, such activities 'may play a valuable role
41 in building a foundation for future reductions' by providing 'necessary catalytic linkages between
42 actors' (Hsu et al. 2019a).

43

44 **14.4.4 Cooperative mechanisms and markets**

45 In theory, trading carbon assets can reduce the costs of global climate mitigation, by helping facilitate
46 abatement of greenhouse gases at least-cost locations. This could help countries ratchet up their

1 ambitions more than in a situation without such mechanisms (Mehling et al. 2018), particularly if
2 mechanisms are scaled up from projects and programmes (Michaelowa et al. 2019b). Progress as to
3 developing such mechanisms has however so far been moderate and uneven.

4 Of the three international market-based mechanisms under the 1997 Kyoto Protocol discussed in
5 Section 14.3.2.7, and in previous IPCC reports, only the CDM or a similar mechanism may have a role
6 to play under the Paris Agreement, although the precise terms are yet to be decided.

7 Article 6, also discussed in Section 14.3.2.7, is the main framework to foster enhanced cooperation
8 within the Paris Agreement. Although there is an emerging global landscape of activities based on
9 Article 6 (Greiner et al. 2020), such as the bilateral treaty signed under the framework of Article 6 in
10 October 2020 by Switzerland and Peru, the possibilities of bilateral cooperation are yet to be fully
11 exploited. As discussed above, adequate accounting rules are key to the success of Article 6. Sectoral
12 agreements are also a promising cooperative mechanism, as discussed in Section 14.5.2. In fact, both
13 bilateral and sectoral agreements have the potential to enhance the ambition of the parties involved and
14 can eventually serve as building blocks towards more comprehensive agreements (see the discussion in
15 Section 14.2.2).

16 A relevant and promising new development is the international linkage of existing regional or national
17 emission trading systems. Several emission trading systems are now operational in different
18 jurisdictions, including the EU, Switzerland, China, South Korea, New Zealand, Kazakhstan and several
19 US states and Canadian provinces (Wettestad and Gulbrandsen 2018). More systems are in the pipeline,
20 including Mexico and Thailand (ICAP 2019). The link between the EU and Switzerland entered into
21 force in January 2020 and other linkages are being negotiated. Scholars analyse the potential benefits
22 of these multilateral linkages and demonstrate that these can be significant (Doda et al. 2019; Doda and
23 Taschini 2017). Over time, the linkages of national emission trading systems can be seen as building
24 blocks to a strategic enlargement of international cooperation (Caparrós and Péreau 2017; Mehling
25 2019). The World Bank has emerged as an important lynchpin and facilitator of knowledge-building
26 and sharing of lessons about the design and linking of carbon markets, through initiatives such as the
27 Partnership for Market Readiness, Networked Carbon Markets and the Carbon Pricing Leadership
28 Coalition (Wettestad et al. 2021).

29 However, it is important to distinguish between theory and practice. The practice of ETS linking so far
30 demonstrates a few attempts that did not result in linkages due to shifts of governments and political
31 preferences (for instance the process between the EU and Australia, and Ontario withdrawing from the
32 WCI) (Bailey and Inderberg 2018). It is worth noting that the linking of carbon markets raises problems
33 of distribution of costs and loss of political control and hence does not offer a politically easy alternative
34 route to a truly international carbon market. Careful, piece-meal and incremental linking may be the
35 most feasible approach forward (Green et al. 2014; Gulbrandsen et al. 2019). It is premature for any
36 serious assessment of the practice of ETS linking to be conducted. Environmental effectiveness,
37 transformative potential, economic performance, institutional strength and even distributional outcomes
38 can potentially be significant and positive if linking is done carefully (Doda and Taschini 2017; Mehling
39 et al. 2018; Doda et al. 2019), but are all marginal if one focuses on existing experiences (Haïtes 2016;
40 Schneider et al. 2017; Spalding-Fecher et al. 2012; La Hoz Theuer et al. 2019; Schneider et al. 2019).

41 42 **14.4.5 International Governance of SRM and CDR**

43 While Solar Radiation Modification (SRM) and Carbon Dioxide Removal (CDR) were often referred
44 to as ‘geoengineering’ in earlier IPCC reports and in the literature, IPCC SR1.5 started to explore SRM
45 and CDR more thoroughly and to highlight the differences between – but also within – both approaches
46 more clearly. This section assesses international governance of both SRM and CDR, recognizing that
47 CDR, as a mitigation option, is covered elsewhere in this report, whereas SRM is not. Chapter 12 of

1 this report covers the emerging national, sub-national and non-state governance of CDR, while chapters
2 6, 7 and 12 also assess the mitigation potential, risks and co-benefits of some CDR options. Chapters 4
3 and 5 of the WGI Report assess the physical climate system and biogeochemical responses to different
4 SRM and CDR methods. The Cross Working Group Box 5 on SRM (WGII, Chapter 16 and Cross-
5 Working Group Box 4 in WGIII below) gives a brief overview of solar radiation modification methods,
6 risks, benefits, ethics and governance.

9 **START CROSS-WORKING GROUP BOX 4 HERE**

11 *Cross-Working Group Box in WGII and Cross-Working Group Box 4 in WGIII*

13 **Cross-Working Group Box 4: Solar Radiation Modification (SRM)**

14 Authors: Govindasamy Bala (India), Heleen de Coninck (the Netherlands), Oliver Geden (Germany),
15 Veronika Ginzburg (the Russian Federation), Katharine J. Mach (the United States of America),
16 Anthony Patt (Switzerland), Sonia I. Seneviratne (Switzerland), Masahiro Sugiyama (Japan),
17 Christopher H. Trisos (Republic of South Africa), Maarten van Aalst (the Netherlands)

18 *Proposed Solar Radiation Modification Schemes*

19 This cross-working group box assesses Solar Radiation Modification (SRM) proposals, their potential
20 contribution to reducing or increasing climate risk, as well as other risks they may pose (categorised as
21 risks from responses to climate change in the IPCC AR6 risk definition in 1.2.1.1), and related
22 perception, ethics and governance questions.

23 SRM refers to proposals to increase the reflection of shortwave radiation (sunlight) back to space to
24 counteract anthropogenic warming and some of its harmful impacts (de Coninck et al. 2018) (Cross-
25 Working Group Box 4; WGI Chapter 4 and Chapter 5). A number of SRM options have been proposed,
26 including: Stratospheric Aerosol Interventions (SAI), Marine Cloud Brightening (MCB), Ground-
27 Based Albedo Modifications (GBAM), and Ocean Albedo Change (OAC). Although not strictly a form
28 of SRM, Cirrus Cloud Thinning (CCT) has been proposed to cool the planet by increasing the escape
29 of longwave thermal radiation to space and is included here for consistency with previous assessments
30 (de Coninck et al. 2018). SAI is the most-researched proposal. Modeling studies show SRM could
31 reduce surface temperatures and potentially ameliorate some climate change risks (with more
32 confidence for SAI than other options), but SRM could also introduce a range of new risks.

33 There is high agreement in the literature that for addressing climate change risks SRM cannot be the
34 main policy response to climate change and is, at best, a supplement to achieving sustained net zero or
35 net negative CO₂ emission levels globally (de Coninck et al. 2018; MacMartin et al. 2018; Buck et al.
36 2020; National Academies of Sciences Engineering and Medicine 2021). SRM contrasts with climate
37 change mitigation activities, such as emission reductions and CDR, as it introduces a ‘mask’ to the
38 climate change problem by altering the Earth’s radiation budget, rather than attempting to address the
39 root cause of the problem, which is the increase in GHGs in the atmosphere. In addition, the effects of
40 proposed SRM options would only last as long as a deployment is maintained—e.g. requiring ca. yearly
41 injection of aerosols in the case of SAI as the lifetime of aerosols in the stratosphere is 1-3 years
42 (Niemeier et al. 2011) or continuous spraying of sea salt in the case of MCB as the lifetime of sea salt
43 aerosols in the atmosphere is only about 10 days—which contrasts with the long lifetime of CO₂ and
44 its climate effects, with global warming resulting from CO₂ emissions likely remaining at a similar level
45 for a hundred years or more (MacDougall et al. 2020) and long-term climate effects of emitted CO₂
46 remaining for several hundreds to thousands of years (Solomon et al. 2009).

47 *Which scenarios?*

1 The choice of SRM deployment scenarios and reference scenarios is crucial in assessment of SRM risks
 2 and its effectiveness in attenuating climate change risks (Keith and MacMartin 2015; Honegger et al.
 3 2021a). Most climate model simulations have used scenarios with highly stylized large SRM forcing to
 4 fully counteract large amounts of warming in order to enhance the signal-to-noise ratio of climate
 5 responses to SRM (Kravitz et al. 2015; Sugiyama et al. 2018a; Krishnamohan et al. 2019).

6 The effects of SRM fundamentally depend on a variety of choices about deployment (Sugiyama et al.
 7 2018b), including: its position in the portfolio of human responses to climate change (e.g., the
 8 magnitude of SRM used against the background radiative forcing), governance of research and potential
 9 deployment strategies, and technical details (latitude, materials, and season, among others, see WGI
 10 Chapter 4.6.3.3). The plausibility of many SRM scenarios is highly contested and not all scenarios are
 11 equally plausible because of socio-political considerations (Talberg et al. 2018), as with, for example,
 12 CDR (Fuss et al. 2014, 2018). Development of scenarios and their selection in assessments should
 13 reflect a diverse set of societal values with public and stakeholder inputs (Sugiyama et al. 2018a; Low
 14 and Honegger 2020), as depending on the focus of a limited climate model simulation, SRM could look
 15 grossly risky or highly beneficial (Pereira et al. 2021).

16 In the context of reaching the long-term global temperature goal of the Paris Agreement, there are
 17 different hypothetical scenarios of SRM deployment: early, substantial mitigation with no SRM, more
 18 limited or delayed mitigation with moderate SRM, unchecked emissions with total reliance on SRM,
 19 and regionally heterogeneous SRM. Each scenario presents different levels and distributions of SRM
 20 benefits, side effects, and risks. The more intense the SRM deployment, the larger is the likelihood for
 21 the risks of side effects and environmental risks (e.g., Heutel et al., 2018). Regional disparities in climate
 22 hazards may result from both regionally-deployed SRM options such as GBAM, and more globally
 23 uniform SRM such as SAI (Jones et al. 2018; Seneviratne et al. 2018). There is an emerging literature
 24 on smaller forcings of SAI to reduce global average warming, for instance, to hold global warming to
 25 1.5°C or 2°C alongside ambitious conventional mitigation (Jones et al. 2018; MacMartin et al. 2018),
 26 or bring down temperature after an overshoot (Tilmes et al. 2020). If emissions reductions and CDR
 27 are deemed insufficient, SRM may be seen by some as the only option left to ensure the achievement
 28 of the Paris Agreement's temperature goal by 2100.

29 **Cross-Working Group Box 4, Table 1: SRM options and their potential climate and non-climate impacts.**
 30 **Description, potential climate impacts, potential impacts on human and natural systems, and termination**
 31 **effects of a number of SRM options: Stratospheric Aerosol Interventions (SAI), Marine Cloud**
 32 **Brightening (MCB), Ocean Albedo Change (OAC), Ground-Based Albedo Modifications (GBAM), and**
 33 **Cirrus Cloud Thinning (CCT).**
 34

SRM option	SAI	MCB	OAC	GBAM	CCT
Description	Injection of reflective aerosol particles directly into the stratosphere or a gas which then converts to aerosols that reflect sunlight	Spraying sea salt or other particles in marine clouds, making them more reflective	Increase surface albedo of the ocean (e.g., by creating microbubbles or placing reflective foam on the surface)	Whitening roofs, changes in land use management (e.g., no-till farming, bioengineering to make crop leaves more reflective), desert albedo enhancement, covering glaciers with reflective sheeting	Seeding to promote nucleation of cirrus clouds, reducing optical thickness and cloud lifetime to allow more outgoing longwave radiation to escape to space
Potential climate impacts <i>other</i>	Change precipitation and runoff	Change in land-sea contrast in	Change in land-sea contrast in	Changes in regional precipitation	Changes in temperature and

<i>than reduced warming</i>	pattern; reduced temperature and precipitation extremes; precipitation reduction in some monsoon regions; decrease in direct and increase in diffuse sunlight at surface; changes to stratospheric dynamics and chemistry; potential delay in ozone hole recovery; changes in surface ozone and UV radiation	temperature and precipitation, regional precipitation and runoff changes	temperature and precipitation, regional , precipitation and runoff changes.	pattern, regional extremes and regional circulation	precipitation pattern, altered regional water cycle, increase in sunlight reaching the surface
Potential impacts on human and natural systems	Changes in crop yields, changes in land and ocean ecosystem productivity, acid rain (if using sulphate), reduced risk of heat stress to corals	Changes in regional ocean productivity, changes in crop yields, reduced heat stress for corals, changes in ecosystem productivity on land, sea salt deposition over land	Unresearched	Altered photosynthesis, carbon uptake and side effects on biodiversity	Altered photosynthesis and carbon uptake
Termination effects	Sudden and sustained termination would result in rapid warming, and abrupt changes to water cycle. Magnitude of termination depends on the degree of warming offset.	Sudden and sustained termination would result in rapid warming, and abrupt changes to water cycle. Magnitude of termination depends on the degree of warming offset.	Sudden and sustained termination would result in rapid warming. Magnitude of termination depends on the degree of warming offset.	GBAM can be maintained over several years without major termination effects because of its regional scale of application. Magnitude of termination depends on the degree of warming offset.	Sudden and sustained termination would result in rapid warming. Magnitude of termination depends on the degree of warming offset.

2 ***SRM risks to human and natural systems and potential for risk reduction***

3 Since AR5, hundreds of climate modelling studies have simulated effects of SRM on climate hazards
4 (Kravitz et al. 2015; Tilmes et al. 2018). Modelling studies have shown SRM has the potential to offset
5 some effects of increasing GHGs on global and regional climate, including the increase in frequency
6 and intensity of extremes of temperature and precipitation, melting of Arctic sea ice and mountain
7 glaciers, weakening of Atlantic meridional overturning circulation, changes in frequency and intensity
8 of tropical cyclones, and decrease in soil moisture (WGI, Chapter 4). However, while SRM may be
9 effective in alleviating anthropogenic climate warming either locally or globally, it would not maintain
10 the climate in a present-day state nor return the climate to a pre-industrial state (climate averaged over
11 1850-1900, See WGI Chapter 1, Box 1.2) in all regions and in all seasons even when used to fully offset
12 the global mean warming (*high confidence*); WGI Chapter 4}. This is because the climate forcing and
13 response to SRM options are different from the forcing and response to GHG increase. Because of these
14 differences in climate forcing and response patterns, the regional and seasonal climates of a world with
15 a global mean warming of 1.5 or 2°C achieved via SRM would be different from a world with similar
16 global mean warming but achieved through mitigation (MacMartin et al. 2018). At the regional scale
17 and seasonal timescale there could be considerable residual climate change and/or overcompensating
18 change (e.g., more cooling, wetting or drying than just what's needed to offset warming, drying or
19 wetting due to anthropogenic greenhouse gas emissions), and there is low confidence in understanding
20 of the climate response to SRM at the regional scale (WGI, Chapter 4).

21 SAI implemented to partially offset warming (e.g., offsetting half of global warming) may have
22 potential to ameliorate hazards in multiple regions and reduce negative residual change, such as drying
23 compared to present-day climate, that are associated with fully offsetting global mean warming (Irvine
24 and Keith 2020), but may also increase flood and drought risk in Europe compared to unmitigated
25 warming (Jones et al. 2021). Recent modelling studies suggest it is conceptually possible to meet
26 multiple climate objectives through optimally designed SRM strategies (WGI, Chapter 4). Nevertheless,
27 large uncertainties still exist for climate processes associated with SRM options (e.g. aerosol-cloud-
28 radiation interaction) (WGI, Chapter 4) (Kravitz and MacMartin 2020).

29 Compared with climate hazards, many fewer studies have examined SRM risks—the potential adverse
30 consequences to people and ecosystems from the combination of climate hazards, exposure and
31 vulnerability—the potential for SRM to reduce risk (Curry et al. 2014; Irvine et al. 2017). Risk
32 analyses have often used inputs from climate models forced with stylized representations of SRM, such
33 as dimming the sun. Fewer have used inputs from climate models that explicitly simulated injection of
34 gases or aerosols into the atmosphere, which include more complex cloud-radiative feedbacks. Most
35 studies have used scenarios where SAI is deployed to hold average global temperature constant despite
36 high emissions.

37 There is *low confidence* and large uncertainty in projected impacts of SRM on crop yields due in part
38 to a limited number of studies. Because SRM would result in only a slight reduction in CO₂
39 concentrations relative to the emission scenario without SRM (Chapter 5, WGI), the CO₂ fertilization
40 effect on plant productivity is nearly the same in emissions scenarios with and without SRM.
41 Nevertheless, changes in climate due to SRM are likely to have some impacts on crop yields. A single

1 study indicates MCB may reduce crop failure rates compared to climate change from a doubling of CO₂
2 pre-industrial concentrations (Parkes et al. 2015). Models suggest SAI cooling would reduce crop
3 productivity at higher latitudes compared to a scenario without SRM by reducing the growing season
4 length, but benefit crop productivity in lower latitudes by reducing heat stress (Pongratz et al. 2012; Xia
5 et al. 2014; Zhan et al. 2019). Crop productivity is also projected to be reduced where SAI reduces
6 rainfall relative to the scenario without SRM, including a case where reduced Asian summer monsoon
7 rainfall causes a reduction in groundnut yields (Xia et al. 2014; Yang et al. 2016). SAI will increase the
8 fraction of diffuse sunlight, which is projected to increase photosynthesis in forested canopy, but will
9 reduce the direct and total available sunlight, which tends to reduce photosynthesis. As total sunlight is
10 reduced, there is a net reduction in crop photosynthesis with the result that any benefits to crops from
11 avoided heat stress may be offset by reduced photosynthesis, as indicated by a single statistical
12 modeling study (Proctor et al. 2018). SAI would reduce average surface ozone concentration (Xia et al.
13 2017) mainly as a result of aerosol-induced reduction in stratospheric ozone in polar regions, resulting
14 in reduced downward transport of ozone to the troposphere (Pitari et al. 2014; Tilmes et al. 2018). The
15 reduction in stratospheric ozone also allows more UV radiation to reach the surface. The reduction in
16 surface ozone, together with an increase in surface UV radiation, would have important implications
17 for crop yields but there is *low confidence* in our understanding of the net impact.

18 Few studies have assessed potential SRM impacts on human health and wellbeing. SAI using sulfate
19 aerosols is projected to deplete the ozone layer, increasing mortality from skin cancer, and SAI could
20 increase particulate matter due to offsetting warming, reduced precipitation and deposition of SAI
21 aerosols, which would increase mortality, but SAI also reduces surface-level ozone exposure, which
22 would reduce mortality from air pollution, with net changes in mortality uncertain and depending on
23 aerosol type and deployment scenario (Effiong and Neitzel 2016; Eastham et al. 2018; Dai et al. 2020).
24 However, these effects may be small compared to changes in risk from infectious disease (e.g.,
25 mosquito-borne illnesses) or food security due to SRM influences on climate (Carlson et al. 2020).
26 Using volcanic eruptions as a natural analog, a sudden implementation of SAI that forced the ENSO
27 system may increase risk of severe cholera outbreaks in Bengal (Trisos et al. 2018; Pinke et al. 2019).
28 Considering only mean annual temperature and precipitation, SAI that stabilizes global temperature at
29 its present-day level is projected to reduce income inequality between countries compared to the highest
30 warming pathway (RCP8.5) (Harding et al. 2020). Some integrated assessment model scenarios have
31 included SAI (Arino et al. 2016; Emmerling and Tavoni 2018; Heutel et al. 2018; Helweggen et al. 2019;
32 Rickels et al. 2020) showing the indirect costs and benefits to welfare dominate, since the direct
33 economic cost of SAI itself is expected to be relatively low (Moriyama et al. 2017; Smith and Wagner
34 2018). There is a general lack of research on the wide scope of potential risk or risk reduction to human
35 health, wellbeing and sustainable development from SRM and on their distribution across countries and
36 vulnerable groups (Carlson et al. 2020; Honegger et al. 2021a).

37 SRM may also introduce novel risks for international collaboration and peace. Conflicting temperature
38 preferences between countries may lead to counter-geoengineering measures such as deliberate release
39 of warming agents or destruction of deployment equipment (Parker et al. 2018). Game-theoretic models
40 and laboratory experiments indicate a powerful actor or group with a higher preference for SRM may
41 use SAI to cool the planet beyond what is socially optimal, imposing welfare losses on others although
42 this cooling does not necessarily imply excluded countries would be worse off relative to a world of
43 unmitigated warming (Ricke et al. 2013; Weitzman 2015; Abatayo et al. 2020). In this context counter-
44 geoengineering may promote international cooperation or lead to large welfare losses (Helweggen et al.
45 2019; Abatayo et al. 2020).

46 Cooling caused by SRM would increase the global land and ocean CO₂ sinks (*medium confidence*), but
47 this would not stop CO₂ from increasing in the atmosphere or affect the resulting ocean acidification
48 under continued anthropogenic emissions (*high confidence*) (WGI Chapter 5).

1 Few studies have assessed potential SRM impacts on ecosystems. SAI and MCB may reduce risk of
2 coral reef bleaching compared to global warming with no SAI (Latham et al. 2013; Kwiatkowski et al.
3 2015), but risks to marine life from ocean acidification would remain, because SRM proposals do not
4 reduce elevated levels of anthropogenic atmospheric CO₂ concentrations. MCB could cause changes in
5 marine net primary productivity by reducing light availability in deployment regions, with important
6 fishing regions off the west coast of South America showing both large increases and decreases in
7 productivity (Partanen et al. 2016; Keller 2018).

8 There is large uncertainty in terrestrial ecosystem responses to SRM. By decoupling increases in
9 atmospheric greenhouse gas concentrations and temperature, SAI could generate substantial impacts on
10 large-scale biogeochemical cycles, with feedbacks to regional and global climate variability and change
11 (Zarnetske et al. 2021). Compared to a high CO₂ world without SRM, global-scale SRM simulations
12 indicate reducing heat stress in low latitudes would increase plant productivity, but cooling would also
13 slow down the process of nitrogen mineralization which could decrease plant productivity (Glienke et
14 al. 2015; Duan et al. 2020). In high latitude and polar regions SRM may limit vegetation growth
15 compared to a high CO₂ world without SRM, but net primary productivity may still be higher than pre-
16 industrial climate (Glienke et al. 2015). Tropical forests cycle more carbon and water than other
17 terrestrial biomes but large areas of the tropics may tip between savanna and tropical forest depending
18 on rainfall and fire (Beer et al. 2010; Staver et al. 2011). Thus, SAI-induced reductions in precipitation
19 in Amazonia and central Africa are expected to change the biogeography of tropical ecosystems in ways
20 different both from present-day climate and global warming without SAI (Simpson et al. 2019;
21 Zarnetske et al. 2021). This would have potentially large consequences for ecosystem services (Chapter
22 2 and Chapter 9). When designing and evaluating SAI scenarios, biome-specific responses need to be
23 considered if SAI approaches are to benefit rather than harm ecosystems. Regional precipitation change
24 and sea salt deposition over land from MCB may increase or decrease primary productivity in tropical
25 rainforests (Muri et al. 2015). SRM that fully offsets warming could reduce the dispersal velocity
26 required for species to track shifting temperature niches whereas partially offsetting warming with SAI
27 would not reduce this risk unless rates of warming were also reduced (Trisos et al. 2018; Dagon and
28 Schrag 2019). SAI may reduce high fire risk weather in Australia, Europe and parts of the Americas,
29 compared to global warming without SAI (Burton et al. 2018). Yet SAI using sulfur injection could
30 shift the spatial distribution of acid-induced aluminum soil toxicity into relatively undisturbed
31 ecosystems in Europe and North America (Visoni et al. 2020). For the same amount of global mean
32 cooling, SAI, MCB, and CCT would have different effects on gross and net primary productivity
33 because of different spatial patterns of temperature, available sunlight, and hydrological cycle changes
34 (Duan et al. 2020). Large-scale modification of land surfaces for GBAM may have strong trade-offs
35 with biodiversity and other ecosystem services, including food security (Seneviratne et al. 2018).
36 Although existing studies indicate SRM will have widespread impacts on ecosystems, risks and
37 potential for risk reduction for marine and terrestrial ecosystems and biodiversity remain largely
38 unknown.

39 A sudden and sustained termination of SRM in a high CO₂ emissions scenario would cause rapid climate
40 change (*high confidence*; WGI Chapter 4). More scenario analysis is needed on the potential likelihood
41 of sudden termination (Kosugi 2013; Irvine and Keith 2020). A gradual phase-out of SRM combined
42 with emission reduction and CDR could avoid these termination effects (*medium confidence*)
43 (MacMartin et al. 2014; Keith and MacMartin 2015; Tilmes et al. 2016). Several studies find that large
44 and extremely rapid warming and abrupt changes to the water cycle would occur within a decade if a
45 sudden termination of SAI occurred (McCusker et al. 2014; Crook et al. 2015). The size of this
46 ‘termination shock’ is proportional to the amount of radiative forcing being masked by SAI. A sudden
47 termination of SAI could place many thousands of species at risk of extinction, because the resulting
48 rapid warming would be too fast for species to track the changing climate (Trisos et al. 2018).

1 ***Public perceptions of SRM***

2 Studies on the public perception of SRM have used multiple methods: questionnaire surveys,
3 workshops, and focus group interviews (Burns et al. 2016; Cummings et al. 2017). Most studies have
4 been limited to Western societies with some exceptions. Studies have repeatedly found that respondents
5 are largely unaware of SRM (Merk et al. 2015). In the context of this general lack of familiarity, the
6 publics prefer carbon dioxide removal (CDR) to SRM (Pidgeon et al. 2012), are very cautious about
7 SRM deployment because of potential environmental side effects and governance concerns, and mostly
8 reject deployment for the foreseeable future. Studies also suggest conditional and reluctant support for
9 research, including proposed field experiments, with conditions of proper governance (Sugiyama et al.
10 2020). Recent studies show that the perception varies with the intensity of deliberation (Merk et al.
11 2019), and that the public distinguishes different funding sources (Nelson et al. 2021). Limited studies
12 for developing countries show a tendency for respondents to be more open to SRM (Visschers et al.
13 2017; Sugiyama et al. 2020), perhaps because they experience climate change more directly (Carr and
14 Yung 2018). In some Anglophone countries, a small portion of the public believes in chemtrail
15 conspiracy theories, which are easily found in social media (Tingley and Wagner 2017; Allgaier 2019).
16 Since researchers rarely distinguish different SRM options in engagement studies, there remains
17 uncertainty in public perception.

18 ***Ethics***

19 There is broad literature on ethical considerations around SRM, mainly stemming from philosophy or
20 political theory, and mainly focused on SAI (Flegal et al. 2019). There is concern that publicly debating,
21 researching and potentially deploying SAI could involve a ‘moral hazard’, with potential to obstruct
22 ongoing and future mitigation efforts (Morrow 2014; Baatz 2016; McLaren 2016), while empirical
23 evidence is limited and mostly at the individual, not societal, level (Burns et al. 2016; Merk et al. 2016,
24 2019). There is low agreement whether research and outdoors experimentation will create a ‘slippery
25 slope’ toward eventual deployment, leading to a lock-in to long-term SRM, or can be effectively
26 regulated at a later stage to avoid undesirable outcomes (Hulme 2014; Parker 2014; Callies 2019;
27 McKinnon 2019). Regarding potential deployment of SRM, procedural, distributive and recognitional
28 conceptions of justice are being explored, (Svoboda and Irvine 2014; Svoboda 2017; Preston and Carr
29 2018; Hourdequin 2019). With the SRM research community’s increasing focus on distributional
30 impacts of SAI, researchers have started more explicitly considering inequality in participation and
31 inclusion of vulnerable countries and marginalized social groups (Flegal and Gupta 2018; Whyte 2018;
32 Táíwò and Talati 2021), including considering stopping research (Stephens and Surprise 2020; National
33 Academies of Sciences Engineering and Medicine 2021). There is recognition that SRM research has
34 been conducted predominantly by a relatively small number of experts in the Global North, and that
35 more can be done to enable participation from diverse peoples and geographies in setting research
36 agendas and research governance priorities, and undertaking research, with initial efforts to this effect
37 (e.g., Rahman et al. 2018), noting unequal power relations in participation could influence SRM
38 research governance and potential implications for policy (Winickoff et al. 2015; Frumhoff and
39 Stephens 2018; Whyte 2018; Biermann and Möller 2019; McLaren and Corry 2021; National
40 Academies of Sciences Engineering and Medicine 2021; Táíwò and Talati 2021).

41 ***Governance of research and of deployment***

42 Currently, there is no dedicated, formal international SRM governance for research, development,
43 demonstration, or deployment (see WGIII Chapter 14). Some multilateral agreements—such as the UN
44 Convention on Biological Diversity or the Vienna Convention on the Protection of the Ozone Layer—
45 indirectly and partially cover SRM, but none is comprehensive and the lack of robust and formal SRM
46 governance poses risks (Ricke et al. 2013; Talberg et al. 2018; Reynolds 2019a). While governance
47 objectives range broadly, from prohibition to enabling research and potentially deployment (Sugiyama
48 et al. 2018b; Gupta et al. 2020), there is agreement that SRM governance should cover all interacting

1 stages of research through to any potential, eventual deployment with rules, institutions, and norms
2 (Reynolds 2019b). Accordingly, governance arrangements are co-evolving with respective SRM
3 technologies across the interacting stages of research, development, demonstration, and—potentially—
4 deployment (Rayner et al. 2013; Parker 2014; Parson 2014). Stakeholders are developing governance
5 already in outdoors research; for example, for MCB and OAC experiments on the Great Barrier Reef
6 (McDonald et al. 2019). Co-evolution of governance and SRM research provides a chance for
7 responsibly developing SRM technologies with broader public participation and political legitimacy,
8 guarding against potential risks and harms relevant across a full range of scenarios, and ensuring that
9 SRM is considered only as a part of a broader portfolio of responses to climate change (Stilgoe 2015;
10 Nicholson et al. 2018). For SAI, large-scale outdoor experiments even with low radiative forcing could
11 be transboundary and those with deployment-scale radiative forcing may not be distinguished from
12 deployment, such that (MacMartin and Kravitz 2019) argue for continued reliance on modeling until a
13 decision on whether and how to deploy is made, with modeling helping governance development. For
14 further discussion of SRM governance see Chapter 14, WGIII.

15 **END CROSS-WORKING GROUP BOX 4 HERE**

17 ***14.4.5.1 Global governance of solar radiation modification and associated risks***

18 Solar Radiation Modification, in the literature also referred to as ‘solar geoengineering’, refers to the
19 intentional modification of the Earth's shortwave radiative budget, such as by increasing the reflection
20 of sunlight back to space, with the aim of reducing warming. Several SRM options have been proposed,
21 including Stratospheric Aerosol Injection (SAI), Marine Cloud Brightening (MCB), Ground-Based
22 Albedo Modifications, and Ocean Albedo Change (OAC). SRM has been discussed as a potential
23 response option within a broader climate risk management strategy, as a supplement to emissions
24 reduction, carbon dioxide removal and adaptation (Crutzen 2006; Shepherd 2009; Caldeira and Bala
25 2017; Buck et al. 2020), for example as a temporary measure to slow the rate of warming (Keith and
26 MacMartin 2015) or address temperature overshoot (MacMartin et al. 2018; Tilmes et al. 2020). SRM
27 assessments of potential benefits and risks still primarily rely on modelling efforts and their underlying
28 scenario assumptions (Sugiyama et al. 2018a), for example in the context of the Geoengineering Model
29 Intercomparison Project GeoMIP6 (Kravitz et al. 2015). Recently, small-scale MCB and OAC
30 experiments started to take place on the Great Barrier Reef (McDonald et al. 2019).

31 Stratospheric aerosol intervention (SAI) – the most researched SRM method – poses significant
32 international governance challenges since it could potentially be deployed uni- or unilaterally and alter
33 the global mean temperature much faster than any other climate policy measure, at comparatively low
34 direct costs (Parson 2014; Nicholson et al. 2018; Smith and Wagner 2018; Sugiyama et al. 2018b;
35 Reynolds 2019a). While being dependent on the design of deployment systems, both geophysical
36 benefits and adverse effects would potentially be unevenly distributed (WGI Chapter 4). Perceived local
37 harm could exacerbate geopolitical conflicts, not the least depending on which countries are part of a
38 deployment coalition (Maas and Scheffran 2012; Zürn and Schäfer 2013), but also because immediate
39 attribution of climatic impacts to detected SAI deployment would not be possible. Uncoordinated or
40 poorly researched deployment by a limited number of states, triggered by perceived climate
41 emergencies, could create international tensions (Corry 2017; Lederer and Kreuter 2018). An additional
42 risk is that of rapid temperature rise following an abrupt end of SAI activities (Parker and Irvine 2018;
43 Rabitz 2019).

44 While there is room for national and even sub-national governance of SAI – for example on research
45 (differentiating indoor from open-air) (Jinnah et al. 2018; Hubert 2020) and public engagement
46 (Bellamy and Lezaun 2017; Flegal et al. 2019) – international governance of SAI faces the challenge
47 that comprehensive institutional architectures designed too far in advance could prove either too
48 restrictive or too permissive in light of subsequent political, institutional, geophysical and technological
49 developments (Sugiyama et al. 2018a; Reynolds 2019a). Views on governance encompass a broad

1 range, from aiming to restrict to wanting to enable research and potentially deployment; in between
2 these poles, other suggest authors stress the operationalization of the precautionary approach:
3 preventing deployment until specific criteria regarding scientific consensus, impact assessments and
4 governance issues are met (Tedsen and Homann 2013; Wieding et al. 2020). Many scholars suggest
5 that governance arrangements ought to co-evolve with respective SRM technologies (Parker 2014),
6 including that it stay at least one step ahead of research, development, demonstration, and—
7 potentially—deployment (Rayner et al. 2013; Parson 2014). With the modelling community's
8 increasing focus on showing that, and in what ways, SAI could help to minimise climate change impacts
9 in the Global South, the SRM governance literature has come to include considerations of how SAI
10 could contribute to global equity (Horton and Keith 2016; Flegal and Gupta 2018; Hourdequin 2018).

11 Given that risks and potential benefits of SRM proposals differ substantially and their large-scale
12 deployment is highly speculative, there is a wide array of concrete proposals for near-term anticipatory
13 or adaptive governance. Numerous authors suggest a wide range of governance principles; (Nicholson
14 et al. 2018) encapsulate most of these in suggesting a list of four: (1) Guard against potential risks and
15 harm; (2) Enable appropriate research and development of scientific knowledge; (3) Legitimise any
16 future research or policymaking through active and informed public and expert community engagement;
17 (4) Ensure that SRM is considered only as a part of a broader, mitigation-centred portfolio of responses
18 to climate change. Regarding international institutionalisation, options range from formal integration
19 into existing UN bodies like the UNFCCC (Nicholson et al. 2018) or the Convention on Biological
20 Diversity (CBD) (Bodle et al. 2014) to the creation of specific, but less formalised global fora (Parson
21 and Ernst 2013) to forms of club governance (Lloyd and Oppenheimer 2014; Bodansky 2013). Recent
22 years have also seen the emergence of transnational non-state actors focusing on SRM governance,
23 primarily expert networks and NGOs (Horton and Koremenos 2020).

24 Currently, there is no targeted international law relating to SRM, although some multilateral
25 agreements—such as the Convention on Biological Diversity, the UN Convention on the Law of the
26 Sea, the Environmental Modification Convention, or the Vienna Convention on the Protection of the
27 Ozone Layer and its Montreal Protocol—contain provisions applicable to SRM (Jinnah and Nicholson
28 2019; Bodansky 2013; Reynolds 2019a).

29 **14.4.5.2 Carbon Dioxide removal**

30 Carbon dioxide removal refers to a cluster of technologies, practices, and approaches that remove and
31 sequester carbon dioxide from the ocean and atmosphere and durably store it in geological, terrestrial,
32 or ocean reservoirs, or in products (see Table 12.6). In contrast to SRM, CDR does not necessarily
33 impose transboundary risks, except insofar as misleading accounting of its use and deployment could
34 give a false picture of countries' overall mitigation efforts. CDR is clearly a form of climate change
35 mitigation, and as described in chapter 12 is needed to counterbalance residual GHG emissions that
36 may prove hard to abate (e.g., from industry, aviation or agriculture) in the context of reaching net zero
37 emissions both globally – in the context of Article 4 of the Paris Agreement – and nationally. CDR
38 could also later be used for reducing atmospheric CO₂ concentrations by providing net negative
39 emissions on the global level (Fuglestvedt et al. 2018; Bellamy and Geden 2019). Despite the common
40 feature of removing carbon dioxide, technologies like afforestation/reforestation, soil carbon
41 sequestration, bioenergy with carbon capture and storage (BECCS), direct air capture with carbon
42 storage, enhanced weathering, ocean alkalinity enhancement or ocean fertilisation are very different, as
43 are the governance challenges. Chapter 12 highlights the sustainable development risks associated with
44 land and water use that are connected to the biological approaches to CDR. As a public good which
45 largely lacks incentives to be pursued as a business case, most types of CDR require a suite of dedicated
46 policy instruments that address both near-term needs as well as long-term continuity at scale (Honegger
47 et al. 2021b).

1 CDR methods other than afforestation/reforestation and soil carbon sequestration have only played a
2 minor role in UNFCCC negotiations so far (Fridahl 2017; Rumpel et al. 2020). To accelerate, and indeed
3 better manage CDR globally, stringent rules and practices regarding emissions accounting, MRV and
4 project-based market mechanisms have been proposed (Honegger and Reiner 2018; Mace et al. 2018).
5 Given their historic responsibility, it can be expected that developed countries would carry the main
6 burden of researching, developing, demonstrating and deploying CDR, or finance such projects in other
7 countries (Poza et al. 2020; Fyson et al. 2020). McLaren et al. (2019) suggest that there is a rationale
8 for separating the international commitments for net negative emissions from those for emission
9 reductions.

10 Specific regulations CDR options have been limited to those posing transboundary risks, namely the
11 use of ocean fertilization. In a series of separate decisions from 2008 - 13, the London Convention /
12 Protocol parties limited ocean fertilization activities to only those of a research character, and in 2012
13 the CBD made a non-legally binding decision to do the same, further requiring such research activities
14 to be limited scale, and carried out under controlled conditions, until more knowledge is gained to be
15 able to assess the risks (GESAMP 2019; Burns and Corbett 2020). In doing so they have taken a
16 precautionary approach (Sands & Peel, 2018). The London Convention/Protocol has also developed an
17 Assessment Framework for Scientific Research Involving Ocean Fertilisation (London
18 Convention/Protocol 2010) and in 2013 adopted amendments (which are not yet in force) to regulate
19 marine carbon dioxide removal activities, including ocean fertilisation.

22 **14.5 Multi-level, multi-actor governance**

23 The Paris Agreement sets in place a new framework for international climate policy (Paroussos et al.
24 2019), which some cite as evidence of ‘hybrid multilateralism’ (Savaresi 2016; Christoff 2016;
25 Bäckstrand et al. 2017). While a trend of widening involvement of non-state actors was evident prior to
26 conclusion of the Paris Agreement, particularly at UNFCCC COPs, the ‘new landscape of international
27 climate cooperation’ features an ‘intensified interplay between state and non-state actors,’ including
28 civil society and social movements, business actors, and subnational or substate actors, such as local
29 governments and cities (Bäckstrand et al. 2017, p. 562). This involvement of other actors beyond states
30 in international climate cooperation is facilitated by the Paris Agreement’s ‘hybrid climate policy
31 architecture’ (Bodansky et al. 2016) (Section 14.3.1.1 above), which acknowledges the primacy of
32 domestic politics in climate change and invites the mobilisation of international and domestic pressure
33 to make the Agreement effective (Falkner 2016b). In this landscape, there is greater flexibility for more
34 decentralised ‘polycentric’ forms of climate governance and recognition of the benefits of working in
35 diverse forms and groups to realise global climate mitigation goals (Oberthür 2016; Jordan et al. 2015)
36 (see also Chapter 1, 1.9) .

37 Increasing attention has focused on the role of multi-level, multi-actor cooperation among actors,
38 groupings and agreements beyond the UNFCCC climate regime as potential ‘building blocks’ towards
39 enhanced international action on climate mitigation (Falkner 2016a; Caparrós and Péreau 2017; Potoski
40 2017; Stewart et al. 2017). This can include agreements on emissions and technologies at the regional
41 or sub-global level; what scholars often refer to as climate club’ (Nordhaus 2015; Hovi et al. 2016;
42 Green 2017; Sprinz et al. 2018). One forum through which such agreements are often discussed, in
43 support of UNFCCC objectives, are high-level meetings of political leaders, such of the G7 and G20
44 states (Livingston 2016). It also includes cooperation on narrower sets of issues than are found within
45 the Paris Agreement; for instance, other international environmental agreements dealing with a
46 particular subset of GHGs; linkages with, or leveraging of, efforts or agreements in other spheres such

1 as adaptation, human rights or trade; agreements within particular economic sectors; or transnational
2 initiatives involving global cooperative efforts by different types of non-state actors. Cooperative efforts
3 in each of these forums are reviewed in the following sections of the chapter. Section 14.5.1 discusses
4 international cooperation at multiple governance levels (global, sub-global and regional); Section 14.5.2
5 discusses cooperation with international sectoral agreements and institutions such as in the forestry,
6 energy and transportation sectors; and Sections 14.5.3-14.5.5 discuss transnational cooperation across
7 civil society and social movements, business partnerships and investor coalitions, and between sub-
8 national entities and cities, respectively.

9 A key idea underpinning this analysis is that decomposition of the larger challenge of climate mitigation
10 into ‘smaller units’ may facilitate more effective cooperation (Sabel and Victor 2017) and complement
11 cooperation in the UN climate regime (Stewart et al. 2017). However, it is recognised that significant
12 uncertainty remains over the feasibility and costs of these efforts (Sabel and Victor 2017), as well as
13 whether they ultimately strengthen progress on climate mitigation in the multilateral climate arena
14 (Falkner 2016a).

15 16 **14.5.1 International cooperation at multiple governance levels**

17 *14.5.1.1 Role of other environmental agreements*

18 International cooperation on climate change mitigation takes place at multiple governance levels,
19 including under a range of multilateral environmental agreements (MEAs) beyond those of the
20 international climate regime.

21 The 1987 Montreal Ozone Protocol is the leading example of a non-climate MEA with significant
22 implications for mitigating climate change (Barrett 2008). The Montreal Protocol regulates a number
23 of substances that are both ozone depleting substances (ODS) and GHGs with a significant global
24 warming potential (GWP), including chlorofluorocarbons, halons and hydrochlorofluorocarbons
25 (HCFCs). As a result, implementation of phase-out requirements for these substances under the
26 Montreal Protocol has made a significant contribution to mitigating climate change (Molina et al. 2009)
27 (See also Section 9.9.7.1). Velders et al. (2007) found that over the period from 1990 to 2010, the
28 reduction in GWP100-weighted ODS emissions expected with compliance to the provisions of the
29 Montreal Protocol was 8 GtCO₂eq yr⁻¹, an amount substantially greater than the first commitment period
30 Kyoto reduction target. Young et al. (2021) suggest that the Montreal Protocol may also be helping to
31 mitigate climate change through avoided decreases in the land carbon sink.

32 The 2016 Kigali Amendment to the Montreal Protocol applies to the production and consumption of
33 hydrofluorocarbons (HFCs). HFCs, which are widely used as refrigerants (Abas et al. 2018), have a
34 high GWP100 of 14600 for HFC-23, and are not ODS (See also Section 9.9.7.1). The Kigali
35 Amendment addresses the risk that the phase-out of HCFCs under the Montreal Protocol and their
36 replacement with HFCs could exacerbate global warming (Akanle 2010; Hurwitz et al. 2016),
37 especially with the predicted growth in HFC usage for applications like air conditioners (Velders et al.
38 2015). In this way it creates a cooperative rather than a conflictual relationship between addressing
39 ozone depletion and the climate protection goals of the UNFCCC regime (Hoch et al. 2019). The Kigali
40 Amendment requires developed country parties to phase down HFCs by 85% from 2011-2013 levels
41 by 2036. Developing country parties are permitted longer phase-down periods (out to 2045 and 2047),
42 but must freeze production and consumption between 2024 and 2028 (Ripley and Verkuil 2016; UN
43 2016). A ban on trade in HFCs with non-parties will come into effect from 1 January 2033. For HFC-
44 23, which is a by-product of HCFC production rather than an ODS, parties are required to report
45 production and consumption data, and to destroy all emissions of HFC-23 occurring as part of HCFCs
46 or HFCs to the extent practicable from 2020 onwards using approved technologies (Ripley and Verkuil
47 2016).

1 Full compliance with the Kigali Amendment is predicted to reduce HFC emissions by 61% of the global
2 baseline by 2050 (Höglund-Isaksson et al. 2017), with avoided global warming in 2100 due to HFCs
3 from a baseline of 0.3-0.5°C to less than 0.1°C (WMO 2018). Examining the interplay of the Kigali
4 Amendment with the Paris Agreement, Hoch et al. (2019) show how the Article 6 mechanisms under
5 the Paris Agreement could generate financial incentives for HFC mitigation and related energy
6 efficiency improvements. Early action under Article 6 of the Paris Agreement could drive down
7 baseline levels of HFCs for developing countries (calculated in light of future production and
8 consumption in the early and mid-2020s) thus generating long-term mitigation benefits under the Kigali
9 Amendment (Hoch et al. 2019). However, achievement of the objectives of the Kigali Amendment is
10 dependent on its ratification by key developed countries, such as the United States, and the provision
11 of funds by developed countries through the Protocol's Multilateral Fund to meet developing countries
12 agreed incremental costs of implementation (Roberts 2017). The Kigali Amendment came into force
13 on 1 January 2019 and has been ratified by 118 of the 198 parties to the Montreal Protocol.

14 MEAs dealing with transboundary air pollution, such as the Convention on Long-Range Transboundary
15 Air Pollution (CLRTAP) and its implementing protocols, which regulate non-GHGs like particulates,
16 nitrogen oxides and ground-level ozone, can also have potential benefits for climate change mitigation
17 (Erickson 2017). Studies have indicated that rigorous air quality controls targeting short-lived climate
18 forcers, like methane, ozone and black carbon, could slow global mean temperature rise by about 0.5°C
19 by mid-century (Schmale et al. 2014). Steps in this direction were taken with 2012 amendments to the
20 CLRTAP Gothenburg Protocol (initially adopted in 1999) to include black carbon, which is an
21 important driver of climate change in the Arctic region (Yamineva and Kulovesi 2018). The amended
22 Protocol, which has 28 parties including the US and EU, entered into force in October 2019. However,
23 its limits on black carbon have been criticised as insufficiently ambitious in light of scientific
24 assessments (Khan and Kulovesi 2018). There is still a non-negligible uncertainty in the assessment of
25 radiative forcing of each Short-Lived Climate Forcers (SLCFs), and the results of AR6-WGI have been
26 updated since AR5. For example, the assessment of Emission-based Radiative Forcing from Black
27 Carbon emissions was revised downward in AR6 (AR6-WGI-6.4.2). When discussing co-benefits with
28 MEAs related to transboundary air pollution, attention should be paid to the uncertainty in radiative
29 forcing of SLCFs and the update of relevant scientific knowledge.

30 Another MEA that may play a role in aiding climate change mitigation is the 2013 Minamata Mercury
31 Convention, which came into force on 16 August 2017. Coal burning for electricity generation
32 represents the second largest source (behind artisanal and small-scale gold mining) of anthropogenic
33 mercury emissions to air (UNEP 2013). Efforts to control and reduce atmospheric emissions of mercury
34 from coal-fired power generation under the Minamata Convention may reduce GHG emissions from
35 this source (Eriksen and Perrez 2014; Selin 2014). For instance, Giang et al. (2015) have modelled the
36 implications of the Minamata Convention for mercury emissions from coal-fired power generation in
37 India and China, concluding that reducing mercury emissions from present-day levels in these countries
38 is likely to require 'avoiding coal consumption and transitioning toward less carbon-intensive energy
39 sources' (Giang et al. 2015). Parties to the Minamata Convention include five of the six top global CO₂
40 emitters – China, the United States, the EU, India and Japan (Russia has not ratified the Convention).
41 The Minamata Convention also establishes an Implementation and Compliance Committee to review
42 compliance with its provisions on a 'facilitative' basis (Eriksen and Perrez 2014).

43 MEAs that require state parties to conserve habitat (such as the Convention on Biological Diversity) or
44 to protect certain ecosystems like wetlands (such as the Ramsar Wetlands Convention) may also have
45 co-benefits for climate change mitigation through the adoption of well-planned conservation policies
46 (Phelps et al. 2012; Gilroy et al. 2014). At a theoretical level, REDD+ activities have been identified as
47 a particular opportunity for achieving climate mitigation objectives while also conserving tropical forest
48 biodiversity and ecosystem services. Elements of REDD+ that promise greatest effectiveness for

1 climate change mitigation (*e.g.* greater finance combined with reference levels which reduce leakage
2 by promoting broad participation across countries with both high and low historical deforestation rates)
3 also offer the greatest benefits for biodiversity conservation (Busch et al. 2011). However, actual
4 biodiversity and ecosystem service co-benefits are dependent on the design and implementation of
5 REDD+ programmes (Ehara et al. 2014; Panfil and Harvey 2016), with limited empirical evidence to
6 date of emissions reductions from these programmes (Newton et al. 2016; Johnson et al. 2019), and
7 concerns about whether they meet equity and justice considerations (Schroeder and McDermott 2014)
8 (See also Chapter 7, section 7.6.1).

9 ***14.5.1.2 Linkages with sustainable development, adaptation, loss and damage, and human rights***

10 As discussed in Chapter 1, the emerging framing for the issue of climate mitigation is that it is no longer
11 to be considered in isolation but rather in the context of its linkages with other areas. Adaptation, loss
12 and damage, human rights and sustainable development are all areas where there are clear or potential
13 overlaps, synergies, and conflicts with the cooperation underway in relation to mitigation.

14 The IPCC defines adaptation as: 'in human systems, the process of adjustment to actual or expected
15 climate and its effects, in order to moderate harm or exploit beneficial opportunities. In natural systems,
16 the process of adjustment to actual climate and its effect; human intervention may facilitate adjustment
17 to expected climate and its effects' (See Annex I: Glossary).

18 Adaptation involves actions to lessen the harm associated with climate change, or take advantage of
19 potential gains (Smit and Wandel 2006). It can seek to reduce present and future exposure to specific
20 climate risks (Adger et al. 2003), mainstream climate information into existing planning efforts (Gupta
21 et al. 2010; van der Voorn et al. 2012, 2017), and reduce vulnerability (or increase resilience) of people
22 or communities to the effects of climate change (Kasperson and Kasperson 2001). There is a body of
23 literature highlighting potential synergies and conflicts between adaptation actions – in any of the three
24 areas above – and mitigation actions - and potential strategies for resolving them (Locatelli et al. 2011;
25 Casado-Asensio and Steurer 2014; Duguma et al. 2014; Suckall et al. 2015; Watkiss et al. 2015; van
26 der Voorn et al. 2020). In a strategic context, this issue has been analyzed in Bayramoglu et al. (2018),
27 Eisenack and Kähler (2016) and Ingham et al. (2013), among others. Bayramoglu et al. (2018) analyze
28 the strategic interaction between mitigation, as a public good, and adaptation, essentially a private good,
29 showing that the fear that adaptation will reduce the incentives to mitigate carbon emissions may not
30 be justified. On the contrary, adaptation can reduce free-rider incentives (lead to larger self-enforcing
31 agreements), yielding higher global mitigation levels and welfare, if adaptation efforts cause mitigation
32 levels between different countries to be complements instead of strategic substitutes (on the conditions
33 for adaptation and mitigation to be substitutes or complements, see (Ingham et al. 2013).

34 Distinct from project or programmatic level activities, however, international cooperation for adaptation
35 operates to provide finance and technical assistance (Bouwer and Aerts 2006). In most cases it involves
36 transboundary actions, such as in the case of transboundary watershed management (Wilder et al. 2010;
37 Milman et al. 2013; van der Voorn et al. 2017). In others it involves the mainstreaming of climate
38 change projections into existing treaties, such as for the protection of migratory species (Trouwborst et
39 al. 2012).

40 International cooperation in mitigation and adaptation share many of the same challenges, including the
41 need for effective institutions. The UNFCCC, for example, addresses international financial support for
42 adaptation and for mitigation in the same general category, and subjects them to the same sets of
43 institutional constraints (Peterson and Skovgaard 2019). Sovacool and Linnér (2016) argue that the
44 history of the UNFCCC and its sub-agreements has been shaped by an implicit bargain that developing
45 countries participate in global mitigation policy in return for receiving financial and technical assistance
46 for adaptation and development from industrialised countries and international green funds. Khan and
47 Roberts (2013) contend that this played out poorly under the Kyoto framework: the Protocol's basic
48 architecture, oriented around legally binding commitments, was not amenable to merging the issues of

1 adaptation and mitigation. Kuyper et al. Kuyper et al. (2018a) argue that the movement from Kyoto to
2 Paris represents a shift in this regard; Paris was designed not primarily as a mitigation policy instrument,
3 but rather one encompassing mitigation, adaptation, and development concerns. While this argument
4 suggests that the Paris architecture, involving voluntary mitigation actions and a greater attention to
5 issues of financial support and transparency, functions better to leverage adaptation support into
6 meaningful mitigation actions, there are only few papers that examine this issue. Stua (2017a,b)
7 explores the relevance of the so-called 'share of proceeds' included in Article 6 of the Paris Agreement
8 as a key tool for leveraging adaptation through mitigation actions.

9 There are recognised limits to adaptation (Dow et al. 2013), and exceeding these limits results in loss
10 and damage, a topic that is gathering salience in the policy discourse. Roberts et al. (2014) focused on
11 'loss and damage', essentially those climate change impacts which cannot be avoided through
12 adaptation. The Paris Agreement contains a free-standing article on loss and damage (UNFCCC 2015a),
13 focused on cooperation and facilitation, under which parties have established a clearing house on risk
14 transfer, and a task force on displacement (UNFCCC 2016a). The COP decision accompanying the
15 Paris Agreement specifies that 'Article 8 does not involve or provide a basis for any liability or
16 compensation' (UNFCCC 2016a). There is range of views on the treatment of loss and damage in the
17 Paris Agreement, how responsibility for loss and damage should be allocated (Lees 2017; McNamara
18 and Jackson 2019), and how it could be financed (Gewirtzman et al. 2018; Roberts et al. 2017). Some
19 scholars argue that there are continuing options to pursue compensation and liability in the climate
20 change regime (Mace and Verheyen 2016; Gsottbauer et al. 2018). There have also been efforts to
21 establish accountability of companies—particularly 'carbon majors'—for climate damage in domestic
22 courts (Ganguly et al. 2018; Benjamin 2021). For states that have suffered loss and damage there is also
23 the option to pursue 'state responsibility' claims under customary international law and international
24 human rights law (Wewerinke-Singh 2018; Wewerinke-Singh and Salili 2020).

25 One scholar argues that climate impacts are 'incremental violence structurally over-determined by
26 international relations of power and control' that affect most those who have contributed the least to
27 GHG emissions (Dehm 2020). Calls for compensation or reparation for loss and damage are therefore
28 a demand for climate justice (Dehm 2020). Many small island states entered declarations on acceptance
29 of the UNFCCC and Paris Agreement that they continue to have rights under international law regarding
30 state responsibility for the adverse effects of climate change, and that no provision in these treaties can
31 be interpreted as derogating from any claims or rights concerning compensation and liability due to the
32 adverse effects of climate change.

33 The adoption in 2013 of the Warsaw International Mechanism on Loss and Damage as part of the United
34 Nations Framework Convention on Climate Change (UNFCCC) occurred despite the historic
35 opposition of the United States to this policy. Vanhala and Hestbaek (2016) examine the roles of 'frame
36 contestation' (contestations over different framings of loss and damage, whether as 'liability and
37 compensation' or 'risk management and insurance' or other) and ambiguity in accounting for the
38 evolution and institutionalisation of the loss and damage norm within the UNFCCC. However, there is
39 little international agreement on the scope of loss and damage programmes, and especially how they
40 would be funded and by whom (Gewirtzman et al. 2018). Moreover, non-economic loss and damage
41 (NELD) forms a distinct theme that refers to the climate-related losses of items both material and
42 non-material that are not commonly traded in the market, but whose loss is still experienced as such
43 by those affected. Examples of NELD include loss of cultural identity, sacred places, human health
44 and lives (Serdeczny 2019). The Santiago Network is part of the Warsaw International Mechanism, to
45 catalyse the technical assistance of relevant organisations, bodies, networks and experts, for the
46 implementation of relevant approaches to avert, minimise and address loss and damage at the local,
47 national and regional level, in developing countries that are particularly vulnerable to the adverse effects
48 of climate change (UNFCCC 2020c).

1 There are direct links between climate mitigation efforts, adaptation and loss and damage - the higher
2 the collective mitigation ambition and the likelihood of achieving it, the lower the scale of adaptation
3 ultimately needed and the lower the scale of loss and damage anticipated. The liability of states, either
4 individually or collectively, for loss and damage is contested, and no litigation has yet been successfully
5 launched to pursue such claims. The science of attribution, however, is developing (Otto et al. 2017;
6 Skeie et al. 2017; Marjanac and Patton 2018; Patton 2021) and while it has the potential to address the
7 thorny issue of causation, and thus compensation (Stuart-Smith et al. 2021), it could also be used to
8 develop strategies for climate resilience (James et al. 2014).

9 There are also direct links between mitigation and sustainable development. The international agendas
10 for mitigation and sustainable development have shaped each other, around concepts such as common
11 but differentiated responsibilities and respective capabilities, as well as the distinction – in the UNFCCC
12 and later the Kyoto Protocol – between Annex I and non-Annex I countries (Victor 2011; Patt 2015).
13 The same implicit bargain that developing countries would support mitigation efforts in return for
14 assistance with respect to adaptation also applies to support for development (Sovacool and Linnér
15 2016). That linkage between mitigation and sustainable development has become even more specific
16 with the Paris Agreement and the 2030 Agenda for Sustainable Development, each of which explicitly
17 pursues a set of goals that encompass both mitigation and development (Schmieg et al. 2017), reflecting
18 the recognition that achieving sustainable development and climate mitigation goals are mutually
19 dependent (Gomez-Echeverri 2018). It is well-accepted that the long-term effects of climate mitigation
20 will benefit sustainable development. A more contested finding is whether the mitigation actions
21 themselves promote or hinder short-term poverty alleviation. One study, analysing the economic effects
22 of developing countries' NDCs, finds that mitigation actions slow down poverty reduction efforts
23 (Campagnolo and Davide 2019). Other studies suggest possible synergies between low-carbon
24 development and economic development (Hanger et al. 2016; Labordena et al. 2017; Dzebo et al. 2019).
25 These studies typically converge on the fact that financial assistance flowing from developed to
26 developing countries enhances any possible synergies or lessens the conflicts. However, mitigation
27 measures can also have negative impacts on gender equality, and peace and justice (Dzebo et al. 2019).
28 The IMF has also taken on board the climate challenge and is examining the role of fiscal and
29 macroeconomic policies to address the climate challenge for supporting its members with appropriate
30 policy responses.

31 The literature also identifies institutional synergies at the international level, related to the importance
32 of addressing climate change and development in an integrated, coordinated and comprehensive manner
33 across constituencies, sectors and administrative and geographical boundaries (Le Blanc 2015). The
34 literature also stresses the important role that robust institutions have in making this happen, including
35 in international cooperation in key sectors for climate action as well for development (Waage et al.
36 2015). Since the publication of AR5, which emphasised the need for a type of development that
37 combines both mitigation and adaptation as a way to strengthen resilience, much of the literature has
38 focused on ways to address these linkages and the role institutions play in key sectors that are often the
39 subject of international cooperation – for example, environmental and soil degradation, climate, energy,
40 water resources, forestry (Hogl et al. 2016). An assessment of thematic policy coherence between the
41 voluntary domestic contributions regarding the Paris Agreement and the 2030 Agenda should be
42 integrated in national policy cycles for sustainable and climate policy-making to identify overlaps, gaps,
43 mutual benefits and trade-offs in national policies (Janetschek et al. 2020).

44 It is only since 2008 that the relationship between climate change and human rights has become a focus
45 of international law and policy making. It is not just climate impacts that threaten the enjoyment of
46 human rights but also the mitigation responses to climate change that affect human rights (Shi et al.
47 2017). The issue of human rights–climate change linkages was first taken up by the UN Human Rights
48 Council (HRC) in 2008, but has since rapidly gained ground with UN human rights treaty bodies issuing

1 comments (e.g. (Human Rights Committee 2018)), recommendations (e.g. (Committee on the
2 Elimination of Discrimination against Women 2018)) and even a joint statement (e.g. (Office of the
3 High Commissioner for Human Rights 2019)) on the impacts of climate change on the enjoyment of
4 human rights. Climate change effects and related disasters have the potential to affect human rights
5 broadly, for instance, by giving rise to deaths, disease or malnutrition (right to life, right to health),
6 threatening food security or livelihoods (right to food), impacting upon water supplies and
7 compromising access to safe drinking water (right to water), destroying coastal settlements through
8 storm surge (right to adequate housing), and in some cases forcing relocation as traditional territories
9 become uninhabitable (UNGA 2019). In addition, the right to a healthy environment, recognized in
10 2021 as an autonomous right at the international level by the Human Rights Council (UN Human Rights
11 Council 2021), arguably extends to a right to a ‘safe climate’ shaped in part by the Paris Agreement
12 (UNGA 2019).

13 As the intersections between climate impacts and human rights have become increasingly clear, litigants
14 have begun to use human rights arguments, with a growing receptivity among courts towards such
15 arguments in climate change cases (Peel and Osofsky 2018; Savaresi and Auz 2019; Macchi and van
16 Zeben 2021). In the landmark Urgenda climate case in 2019, the Dutch Supreme Court interpreted the
17 European Convention on Human Rights in light of customary international law and the UN climate
18 change regime and ordered the state to reduce greenhouse gas emissions by 25% by 2020 compared to
19 1990 (The Supreme Court of the Netherlands 2019). In the Neubauer case in 2021, the German Federal
20 Constitutional Court ordered the German legislature, in light of its obligations, including on rights
21 protections, to set clear provisions for reduction targets from 2031 onward by the end of 2022 (German
22 Constitutional Court 2021). There are cases in the Global South as well (Peel and Lin 2019; Setzer and
23 Benjamin 2020), with the Supreme Court in Nepal in its 2018 decision in Shrestha, ordering the
24 government to amend its existing laws and introduce a new consolidated law to address climate
25 mitigation and adaptation as this would protect the rights to life, food, and a clean environment, and
26 give effect to the 2015 Paris Agreement (The Supreme Court of Nepal 2018). There are dozens of
27 further cases in national and regional courts, increasingly based on human rights claims. and this trend
28 is only likely to grow (Beauregard et al. 2021; Shi et al. 2017; Peel and Osofsky 2018). These cases
29 face procedural hurdles, such as standing, as well as substantive difficulties, for instance, with regard
30 to the primarily territorial scope of state obligations to protect human rights (Mayer 2021; Boyle 2018),
31 however, there are increasing instances of successful outcomes across the world.

32 *14.5.1.3 Trade agreements*

33 As discussed in AR5, policies to open up trade can have a range of effects on GHG emissions, just as
34 mitigation policies can influence trade flows among countries. Trade rules may impede mitigation
35 action by limiting countries’ discretion in adopting trade-related climate policies, but they also have the
36 potential to stimulate the international adoption and diffusion of mitigation technologies and policies
37 (Droege et al. 2017).

38 The mitigation impacts of trade agreements are difficult to ascertain, and the limited evidence is mixed.
39 Examining the effects of three free trade agreements (FTAs) – Mercosur, the North American Free
40 Trade Agreement (NAFTA) and the Australia-United States Free Trade Agreement – on GHG
41 emissions, (Nemati et al. 2019) find that these effects depend on the relative income levels of the
42 countries involved, and that FTAs between developed and developing countries may increase emissions
43 in the long run. However, studies also suggest that FTAs incorporating specific environmental or
44 climate-related provisions can help reduce GHG emissions (Baghdadi et al. 2013; Sorgho and Tharakan
45 2020).

46 Investment agreements, which are often integrated in FTAs, seek to encourage the flow of foreign
47 investment through investment protection. While international investment agreements hold potential to
48 increase low-carbon investment in host countries (PAGE 2018), these agreements have tended to protect

1 investor rights, constraining the latitude of host countries in adopting environmental policies (Miles
2 2019). Moreover, international investment agreements may lead to ‘regulatory chill’, which may lead
3 to countries refraining from or delaying the adoption of mitigation policies, such as phasing out fossil
4 fuels (Tienhaara 2018). More contemporary investment agreements seek to better balance the rights and
5 obligations of investors and host countries, and in theory offer greater regulatory space to host countries
6 (UNCTAD 2019), although it is unclear to what extent this will hold true in practice.

7 In their NDCs, parties mention various trade-related mitigation measures, including import bans,
8 standards and labelling schemes, border carbon adjustments (BCAs; see also Chapter 13), renewable
9 energy support measures, fossil fuel subsidy reform, and the use of international market mechanisms
10 (Brandi 2017). Some of these ‘response measures’ (Chan 2016b) may raise questions concerning their
11 consistency with trade agreements of the World Trade Organisation (WTO). Non-discrimination is one
12 of the foundational rules of the WTO. This means, among others, that ‘like’ imported and domestic
13 products are not treated differently (‘national treatment’) and that a WTO member should not
14 discriminate between other members (‘most-favoured-nation treatment’). These principles are
15 elaborated in a set of agreements on the trade in goods and services, including the General Agreement
16 on Tariffs and Trade (GATT), the General Agreement on Trade in Services (GATS), the Agreement on
17 Technical Barriers to Trade (TBT), and the Agreement on Subsidies and Countervailing Measures
18 (ASCM).

19 Several measures that can be adopted as part of carbon pricing instruments to address carbon leakage
20 concerns have been examined in the light of WTO rules. For instance, depending on the specific design,
21 the free allocation of emissions allowances under an ETS could be considered a subsidy inconsistent
22 with the ASCM (Rubini and Jegou 2012; Ismer et al. 2021). The WTO compatibility of another measure
23 to counter carbon leakage, BCAs, has also been widely discussed (Box 14.2). Alternatives to BCAs,
24 such as consumption charges on carbon-intensive materials (Pollitt et al. 2020), can be consistent with
25 WTO law, as they do not involve discrimination between domestic and foreign products based on their
26 carbon intensity (Ismer and Neuhoff 2007; Tamiotti 2011; Pauwelyn 2013; Holzer 2014; Ismer and
27 Haussner 2016; Cosbey et al. 2019; European Commission 2019; Mehling et al. 2019; Porterfield 2019;
28 Ismer et al. 2020).

29

30 **START BOX 14.2 HERE**

31 **Box 14.2 Border carbon adjustments and international climate and trade cooperation**

32 Analyses of the WTO compatibility of BCAs (Hillman 2013; Trachtman 2017; Ismer and Neuhoff
33 2007; Tamiotti 2011; Pauwelyn 2013; Holzer 2014; Cosbey et al. 2019; Mehling et al. 2019; Porterfield
34 2019) gained new currency following the legislative proposal to introduce a ‘carbon border adjustment
35 mechanism’ in the EU (European Commission 2021). BCAs can in principle be designed and
36 implemented in accordance with international trade law, but the details matter (Tamiotti et al. 2009).
37 To increase the likelihood that a BCA will be compatible with international trade law, studies suggest
38 that it would need to: have a clear environmental rationale (i.e. reduce carbon leakage); apply to imports
39 and exclude exports; consider the actual carbon intensity of foreign producers; account for the
40 mitigation efforts by other countries; and provide for fairness and due process in the design and
41 implementation (Trachtman 2017; Pauwelyn 2013; Cosbey et al. 2019; Mehling et al. 2019).

42 BCAs may also raise concerns regarding their consistency with international climate change agreements
43 (Hertel 2011; Davidson Ladly 2012; Ravikumar 2020). To mitigate these concerns, BCAs could include
44 special provisions (e.g. exemptions) for LDCs, or channel revenues from the BCA to developing
45 countries to support low-carbon and climate-resilient development (Grubb 2011; Springmann 2013;
46 Mehling et al. 2019). Moreover, international dialogue on principles and best practices guiding BCAs

1 could help to ensure that such measures do not hinder international cooperation on climate change and
2 trade (Bernasconi-Osterwalder and Cosbey 2021).

3 **END BOX 14.2 HERE**

4

5 Other regulatory measures may also target the GHG emissions associated with the production of goods
6 (Dobson 2018). These measures include bans on carbon-intensive materials, emissions standards for
7 the production process of imported goods, and carbon footprint labels (Kloeckner 2012; Holzer and
8 Lim 2020; Gerres et al. 2021). The compatibility of such measures with trade agreements remains
9 subject to debate. While non-discriminatory measures targeting the emissions from a product itself (e.g.
10 fuel efficiency standards for cars) are more likely to be allowed than measures targeting the production
11 process of a good (Green 2005), some studies suggest that differentiation between products based on
12 their production process may be compatible with WTO rules (Benoit 2011; McAusland and Najjar
13 2015). (Mayr et al. 2020) find that sustainability standards targeting the emissions from indirect land-
14 use change associated with the production of biofuels may be inconsistent with the TBT Agreement.
15 Importantly, trade rules express a strong preference for the international harmonisation of standards
16 over unilateral measures (Delimatsis 2016).

17 Renewable energy support measures may be at odds with the ASCM, the GATT, and the WTO
18 Agreement on Trade-Related Investment Measures. In WTO disputes, measures adopted in Canada,
19 India, and the United States to support clean energy generation were found to be inconsistent with WTO
20 law due to the use of discriminatory local content requirements, such as the requirement to use
21 domestically produced goods in the production of renewable energy (Cosbey and Mavroidis 2014;
22 Kulovesi 2014; Lewis 2014; Wu and Salzman 2014; Charnovitz and Fischer 2015; Shadikhodjaev 2015;
23 Espaa and Marín Durán 2018).

24 Some measures may both lower trade barriers and potentially bring about GHG emission reductions.
25 An example is the liberalisation of trade in environmental goods (Hu et al. 2020). In 2012, the APEC
26 economies agreed to reduce tariffs for a list of 54 environmental goods (including e.g. solar cells; but
27 excluding e.g. biofuels or batteries for electric vehicles). However, negotiations on an Environmental
28 Goods Agreement under the WTO stalled in 2016 due in part to disagreement over which goods to
29 include (de Melo and Solleder 2020). Another example is fossil fuel subsidy reform, which may reduce
30 GHG emissions (Jewell et al. 2018; Chepeliev and van der Mensbrugge 2020; Erickson et al. 2020)
31 and lower trade distortions (Burniaux et al. 2011; Moerenhout and Irschlenger 2020). However, fossil
32 fuel subsidies have largely remained unchallenged before the WTO due to legal and political hurdles
33 (Asmelash 2015; De Bièvre et al. 2017; Meyer 2017; Steenblik et al. 2018; Verkuijl et al. 2019).

34 With limited progress in the multilateral trading system, some studies suggest that regional FTAs hold
35 potential for strengthening climate governance. In some cases, climate-related provisions in such FTAs
36 can go beyond provisions in the Kyoto Protocol and Paris Agreement, addressing for instance
37 cooperation on carbon markets or electric vehicles (Gehring et al. 2013; van Asselt 2017; Morin and
38 Jinnah 2018; Gehring and Morison 2020). However, Morin and Jinnah (2018) find that these provisions
39 are at times vaguely formulated, not subject to third-party dispute settlement, and without sanctions or
40 remedy in case of violations. Moreover, such provisions are not widely used in FTAs, and they are not
41 adopted by the largest GHG emitters. For instance, the 2019 United States-Mexico-Canada Agreement,
42 NAFTA's successor, does not include any specific provisions on climate change, although it could
43 implement cooperative mitigation actions through its Commission for Environmental Cooperation
44 (Laurens et al. 2019).

45 A trend in international economic governance has been the adoption of 'mega-regional' trade
46 agreements involving nations responsible for a substantial share of world trade, such as the
47 Comprehensive and Progressive Agreement for Trans-Pacific Partnership (CPTPP), the EU-Canada

1 Comprehensive Economic and Trade Agreement (CETA), and the Regional Comprehensive Economic
2 Partnership (RCEP) in East Asia. Given the size of the markets covered by these agreements, they hold
3 potential to diffuse climate mitigation standards (Meltzer 2013; Holzer and Cottier 2015). While CETA
4 includes climate-related provisions and parties have made a broad commitment to implement the Paris
5 Agreement (Laurens et al. 2019), and the CPTPP includes provisions promoting cooperation on clean
6 energy and low-emissions technologies, the RCEP does not include specific provisions on climate
7 change.

8 Studies have discussed various options to minimise conflicts, and strengthen the role of trade
9 agreements in climate action, although the mitigation benefits and distributional effects of these options
10 have yet to be assessed. Some options require multilateral action, including: (1) the amendment of
11 WTO agreements to accommodate climate action; (2) the adoption of a ‘climate waiver’ that
12 temporarily relieves WTO members from their obligations; (3) a ‘peace clause’ through which members
13 commit to refraining from challenging each other’s measures; (4) an ‘authoritative interpretation’ by
14 WTO members of ambiguous WTO provisions; (5) improved transparency of the climate impacts of
15 trade measures; (6) the inclusion of climate expertise in WTO disputes; and (7) intensified institutional
16 coordination between the WTO and UNFCCC (Hufbauer et al. 2009; Epps and Green 2010; Bacchus
17 2016; Droege et al. 2017; Das et al. 2019). In addition, issue-specific suggestions have been put forward,
18 such as reinstating an exception for environmentally motivated subsidies under the ASCM (Horlick and
19 Clarke 2017).

20 Options can also be pursued at the plurilateral and regional level. Several studies suggest that climate
21 clubs (see Section 14.2.2) could employ trade measures, such as lower tariffs for climate-related goods
22 and services, or BCAs, to attract club members (Nordhaus 2015; Brewer et al. 2016; Keohane et al.
23 2017; Stua 2017a; Banks and Fitzgerald 2020). Another option is to negotiate a new agreement
24 addressing both climate change and trade. Negotiations between six countries (Costa Rica, Fiji, Iceland,
25 New Zealand, Norway, Switzerland) were launched in 2019 on a new Agreement on Climate Change,
26 Trade and Sustainability (ACCTS), which, if successfully concluded, would liberalise trade in
27 environmental goods and services, create new rules to remove fossil fuel subsidies, and develop
28 guidelines for voluntary eco-labels (Steenblik and Droege 2019). At the regional level, countries could
29 further opt for the inclusion of climate provisions in the (re)negotiation of FTAs (Yamaguchi 2020;
30 Morin and Jinnah 2018). Moreover, the conduct of climate impact assessments of FTAs could help
31 identify options to achieve both climate and trade objectives (Porterfield et al. 2017). In their assessment
32 of the feasibility of various options for reform, Das et al. (2019) find that the near-term feasibility of
33 options that require consensus at the multilateral level (notably amendments of WTO agreements) is
34 low. By contrast, options involving a smaller number of parties, as well as options that can be
35 implemented by WTO members on a voluntary basis, face fewer constraints.

36 For international investment agreements, various other suggestions have been put forward to
37 accommodate climate change concerns. These include incorporating climate change through ongoing
38 reform processes, such as reform of investor-state dispute settlement under the UN Commission on
39 International Trade Law (UNCITRAL); modernisation of the Energy Charter Treaty; the (re)negotiation
40 of international investment agreements; and the adoption of a specific treaty to promote investment in
41 climate action (Brauch et al. 2019; Tienhaara and Cotula 2020; Yamaguchi 2020; Cima 2021).

42 **14.5.1.4 South-South cooperation**

43 South-South (SSC) and triangular (TrC) cooperation are bold, innovative, and rapidly developing means
44 of strengthening cooperation for the achievement of the SDGs (FAO 2018). SSC is gaining momentum
45 in achieving sustainable development and climate actions in developing countries (UN 2017b). Through
46 SSC, countries are able to map their capacity needs and knowledge gaps and find sustainable, cost-
47 effective, long-lasting and economically viable solutions (FAO 2019). In the UN Climate Change

1 Engagement Strategy 2017 (UNOSC 2017), South-South Cooperation Action Plan is identified as a
2 substantive pillar to support.

3 In 2019, the role of South-South and triangular cooperation was further highlighted with the BAPA+40
4 Outcome document (UN 2019), noting outstanding contributions to alleviating global inequality,
5 promoting sustainable development and climate actions, promoting gender equality and enriching
6 multilateral mechanisms. Furthermore, the role of triangular cooperation was explicitly recognized in
7 the document reflecting its increasingly relevant role in the implementation of the SDGs (UN 2019).

8 There has been a recent resurgence of South-South cooperation. Gray and Gills (Gray and Gills 2016),
9 signalled inter alia by the South-South Cooperation Action Plan adopted by the UN as a substantive
10 pillar to support the implementation of the UN Climate Change Engagement Strategy 2017 (UNOSC
11 2017). (Liu et al. 2017a) explored prospects for South–South cooperation for large-scale ecological
12 restoration, which is an important solution to mitigate climate change. Emphasis is given to experience
13 and expertise sharing, co-financing, and co-development of new knowledge and know-how for more
14 effective policy and practice worldwide, especially in developing and newly industrialised countries.

15 Janus et al. (2014) explore evolving development cooperation and its future governance architecture
16 based on The Global Partnership for Effective Development Cooperation (GPEDC) and The United
17 Nations (UN) Development Cooperation Forum (DCF). Drawing on evidence from the hydropower,
18 solar and wind energy industry in China, Urban (2018) introduces the concept of ‘geographies of
19 technology transfer and cooperation’ and challenges the North-South technology transfer and
20 cooperation paradigm for low carbon innovation and climate change mitigation. While North-South
21 technology transfer and cooperation (NSTT) for low carbon energy technology has been implemented
22 for decades, South-South technology transfer and cooperation (SSTT) and South-North technology
23 transfer and cooperation (SNTT) have only recently emerged. Kirchherr and Urban (2018) provide a
24 meta-synthesis of the scholarly writings on NSTT, SSTT and SNTT from the past 30 years. The
25 discussion focuses on core drivers and inhibitors of technology transfer and cooperation, outcomes as
26 well as outcome determinants. A case study of transfer of low-carbon energy innovation and its
27 opportunities and barriers, based on first large Chinese-funded and Chinese-built dam in Cambodia is
28 presented by Hensengerth (2017).

29 Hensengerth (2017) explore the role that technology transfer/cooperation from Europe played in
30 shaping firm level wind energy technologies in China and India and discuss the recent technology
31 cooperation between the Chinese, Indian, and European wind firms. The research finds that firm-level
32 technology transfer/cooperation shaped the leading wind energy technologies in China and to a lesser
33 extent in India. Thus, the technology cooperation between China, India, and Europe has become multi-
34 faceted and increasingly Southern-led.

35 Rampa et al. (2012) focus on the manner in which African states understand and approach new
36 opportunities for cooperation with emerging powers, especially China, India and Brazil, including the
37 crucial issue of whether they seek joint development initiatives with both traditional partners and
38 emerging powers. UN (2018) presents and analyses case studies of SSTT in Asia-Pacific and Latin
39 America and Caribbean regions. Illustrative case studies on TrC can be consulted in Shimoda and
40 Nakazawa (2012), and specific cases on biofuel SSC and TrC in UNCTAD (2012).

41 The central argument in the majority of these case studies is that South–South cooperation, which is
42 value-neutral, is contributing to sustainable development and capacity building (Rampa et al. 2012;
43 Shimoda and Nakazawa 2012; UN 2018). An important new development in SSC is that in relation to
44 some technologies the cooperation is increasingly led by Southern countries (for instance, wind energy
45 between Europe, India and China), challenging the classical North–South technology cooperation
46 paradigm. More broadly, parties should ensure the sustainability of cooperation, rather than focusing
47 on short-term goals (Eyben 2013). The Belt and Road Initiative (BRI) is a classic example of a recent

1 SSC Initiative led by China. According to a joint study by Tsinghua University and Vivid Economics
2 the 126 countries in the BRI region, excluding China, currently account for about 28% of global GHG
3 emissions, but this proportion may increase to around 66% by 2050 if the carbon intensity of these
4 economies only decreases slowly (according to historical patterns shown by developing countries). In
5 this context it is important to highlight that China has already outlined a vision for a green BRI, and
6 recently increased its commitment through the Green Investment Principles (GIP) initiative, announcing
7 a new international coalition to improve sustainability and promote green infrastructure (Jun and Zadek
8 2019).

9 Information on triangular cooperation is more readily available than on South-South cooperation though
10 some UN organisations such as UNDP and FAO have established platforms for the latter which also
11 includes climate projects. Further, although there are many South-South cooperation initiatives
12 involving the development and transfer of climate technologies the understanding of the motivations,
13 approaches and designs is limited and not easily accessible. There is no dedicated platform for South-
14 South and triangular cooperation on climate technologies. Hence, it is still too early to fully assess the
15 achievements in the field of climate action (UNFCCC and UNOSSC 2018). In order to maximise its
16 unique contribution to Agenda 2030, southern providers recognise the benefits of measuring and
17 monitoring South–South cooperation, and there is a clear demand for better information from partner
18 countries. Di Ciommo (2017) argues that ‘better data could support monitoring and evaluation, improve
19 effectiveness, explore synergies with other resources, and ensure accountability’ to a diverse set of
20 stakeholders. Besharati et al. (2017) present a framework of 20 indicators, organised in five dimensions
21 that researchers and policy makers can use to assess the quality and effectiveness of SSC and its
22 contribution to sustainable development.

23 The global landscape of development cooperation has changed dramatically in recent years, with
24 countries of the South engaging in collaborative learning models to share innovative, adaptable and
25 cost-efficient solutions to their development and socio-economic-environmental challenges, ranging
26 from poverty and education to climate change. The proliferation of new actors and cross-regional
27 modalities had enriched the understanding and practice of development cooperation and generated
28 important changes in the global development architecture towards a more inclusive, effective, and
29 horizontal development agenda. South-South cooperation will grow in the future, while it is
30 complimentary to North-South cooperation. However, there are knowledge gaps in relation to the
31 precise volume, impact, effectiveness and quality of development cooperation from emerging
32 development partners. This gap needs to be plugged, and evidence on such cooperation strengthened.

34 **14.5.2 International sectoral agreements and institutions**

35 Sectors refer to distinct areas of economic activity, often subject to their own governance regimes;
36 examples include energy production, mobility, and manufacturing. A sectoral agreement could include
37 virtually any type of commitment with implications for mitigation. It could establish sectoral emission
38 targets, on either an absolute or an indexed basis. It could also require states (or particular groups of
39 states, if commitments are differentiated) to adopt uniform or harmonised policies and measures for a
40 sector, such as technology-based standards, taxes, or best-practice standards, as well as providing for
41 cooperation on technology research or deployment.

42 **14.5.2.1 Forestry, land-use and REDD+**

43 Since 2008, several, often overlapping, voluntary and non-binding international efforts and agreements
44 have been adopted to reduce net emissions from the forestry sector. These initiatives have varying levels
45 of private sector involvement and different objectives, targets, and timelines. Some efforts focus on
46 reducing emissions from deforestation and degradation, while other focus on the enhancement of sinks
47 through restoration of cleared or degraded landscapes. These initiatives do not elaborate specific

1 policies, procedures, or implementation mechanisms. They set targets, frameworks, and milestones,
2 aiming to catalyse further action, investment, and transparency in conservation and consolidate
3 individual country efforts.

4 After the UN-sponsored Tropical Forestry Action Plan (Winterbottom 1990; Seymour and Busch 2016),
5 among the longest standing programs in the forestry sector are the World Bank-sponsored F Forest
6 Carbon Partnership Facility in 2007, which helps facilitate funding for REDD+ readiness and specific
7 projects, in addition to preparing countries for results-based payments and future carbon markets while
8 securing local communities' benefits managed sub-nationally, and the UN REDD+ Programme
9 initiated in 2008, which aims to reduce forest emissions and enhance carbon stocks in forests while
10 contributing to national sustainable development in developing countries, after the 2007 COP13 in Bali
11 formally adopted REDD+ in the UNFCCC decisions and incorporated it in the Bali Plan of Action. As
12 discussed above, Article 5 of the Paris Agreement encourages parties to take action to implement and
13 support REDD+. These efforts tend to focus on reducing emissions through the creation of protected
14 areas, payments for ecosystem services, and/or land tenure reform (Pirard et al. 2019). The UNREDD+
15 programme supports national REDD+ efforts, inclusion of stakeholders in relevant dialogues, and
16 capacity building toward REDD+ readiness in partner countries. To date the conservation and emissions
17 impacts of REDD+ remain misunderstood (Pirard et al. 2019), but while existing evidence suggests that
18 reductions in deforestation from subnational REDD+ initiatives have been limited (Bos et al. 2017) it
19 shows an increasing prominence (Maguire et al. 2021). Additionally, the Green Climate Fund has
20 carried out results-based payments within REDD+. Eight countries have so far received significant
21 funding (GCF 2021). The shift in the REDD+ focus from ecosystem service payment to domestic policy
22 realignments and incentive structure has changed the way REDD+ was developed and implemented
23 (Brockhaus et al. 2017). Large-scale market resources have not fully materialised as a global carbon
24 market system that explicitly integrates REDD+ remains under development (Angelsen 2017). Public
25 funding for REDD+ is also limited (Climate Focus 2017). Leading up to the adoption of the Paris
26 Agreement, the governments of Germany, Norway, and the United Kingdom formed a partnership in
27 2014 called 'GNU' to support results-based financing for REDD+, with Norway emerging as one of, if
28 not the single largest major donor for REDD+ through its pledge in 2007 of approximately USD3 billion
29 annually. Norway pledged USD1 billion for Brazil in 2008 and the same for Indonesia in 2010
30 (Schroeder et al. 2020). Meanwhile, REDD+ Early Movers was established with support from
31 Germany, and the Central African Forest Initiative (CAFI), a collaborative partnership between the
32 European Union, Germany, Norway, France, and the United Kingdom. It supports six central African
33 countries in fighting deforestation.

34 More recently, the Lowering Emissions by Accelerating Forest Finance (LEAF) Coalition was
35 established, consisting of the governments of Norway, the UK, and the US and initially nine companies
36 in accelerating REDD+ with a jurisdictional approach. LEAF uses the Architecture for REDD+
37 Transaction, The REDD+ Environmental Excellence Standard (ART-TREES), is coordinated by
38 Emergent, a non-profit intermediary between tropical countries and the private sector. Three
39 jurisdictions in Brazil and two countries have already submitted concept notes to ART to receive results-
40 based payments. REDD+ initiatives with a jurisdictional approach have also been adopted in various
41 markets, such as the CORSIA (Maguire 2021). In addition to Brazil, Indonesia has attracted significant
42 interest as a host country for REDD+. Indonesia ranks second, after Brazil, as the largest producer of
43 deforestation-related GHG emissions (Zarin et al. 2016), but it has committed to a large reduction of
44 deforestation in its NDC (Government of Indonesia 2016). Australia has collaborated on scientific
45 research and emission reduction monitoring (Tacconi 2017). It took a while, however, before emission
46 reductions were witnessed (Meehan et al. 2019). The expansion of commodity plantations, however,
47 conflict with reduction ambitions (Anderson et al. 2016; Irawan et al. 2019) In addition to
48 implementation at the site and jurisdictional levels, legal enforcement (Tacconi et al. 2019) as well as
49 policy and regulatory reforms (Ekawati et al. 2019) appears to be needed.

1 Another relevant initiative is one under the 2015 United Nations Convention to Combat Desertification
2 (UNCCD), which targets land degradation neutrality i.e., ‘a state whereby the amount and quality of
3 land resources, necessary to support ecosystem functions and services and enhance food security,
4 remains stable or increases within specified temporal and spatial scales and ecosystems’ (Orr et al.
5 2017). This overarching goal was recognised as also being critical to reaching the more specific avoided
6 deforestation and degradation and restoration goals of the UNFCCC and UNCBD. The Land
7 Degradation Neutrality (LDN) initiative from UNCCD includes target setting programmes (TSP) that
8 assist countries by providing practical tools and guidance for the establishment of the voluntary targets
9 and formulate associated measures to achieve LDN and accelerate implementation of projects (Chasek
10 et al. 2019). Today, 124 countries have committed to their LDN national targets (UNCCD 2015). The
11 LDN Fund is an investment vehicle launched in UNCCD COP 13 in 2017, which exists to provide long-
12 term financing for private projects and programmes for countries to achieve their LDN targets.
13 According to the UNCCD, most of the funds will be invested in developing countries.

14 Recent efforts towards the enhancement of sinks from the forestry sector have the overarching goal of
15 reaching zero *gross* deforestation globally, i.e., eliminating the clearing of all natural forests. The New
16 York Declaration on Forests (NYDF) was the first international pledge to call for a halving of natural
17 forest loss by 2020 and the complete elimination of natural forest loss by 2030 (Climate Focus 2016).
18 It was endorsed at the United Nations Climate Summit in September 2014. By September 2019 the list
19 of NYDF supporters included over 200 actors: national governments, sub-national governments, multi-
20 national companies, groups representing indigenous communities, and non-government organisations.
21 These endorsers have committed to doing their part to achieve the NYDF’s ten goals, which include
22 ending deforestation for agricultural expansion by 2020, reducing deforestation from other sectors,
23 restoring forests, and providing financing for forest action (Forest Declaration 2019). These goals are
24 assessed and tracked through the NYDF Progress Assessment, which includes NYDF Assessment
25 Partners that collect data, generate analysis, and release the finding based on the NYDF framework and
26 goals.

27 The effectiveness of these agreements, which lack binding rules, can only be judged by the
28 supplementary actions they have catalysed. The NYDF contributed to the development of several other
29 zero-deforestation pledges, including the Amsterdam Declarations by seven European nations to
30 achieve fully sustainable and deforestation-free agro-commodity supply chains in Europe by 2020 and
31 over 150 individual company commitments to not source products associated with deforestation
32 (Donofrio et al. 2017; Lambin et al. 2018). Recent studies indicate that these efforts currently lack the
33 potential to achieve wide-scale reductions in clearing and associated emissions due to weak
34 implementation (Garrett et al. 2019), although in some cases in Indonesia and elsewhere the commodity
35 supply chain sustainability drive appears to contribute to lowering deforestation (Wijaya et al. 2019;
36 Chain Reaction Research 2020; Schulte et al. 2020). The NYDF may have triggered small additional
37 reductions in deforestation in some areas, particularly for soy, and to a lesser extent cattle, in the
38 Brazilian Amazon (Lambin et al. 2018), but these effects were temporary, as efforts are being actively
39 reversed and deforestation has increased again significantly. Deforestation rates have escalated in
40 Brazil, with the rate in June 2019 (the first dry-season month in the new administration) up 88% over
41 the 2018 rate in the same month (INPE 2019). Curtis et al. (2018) find global targets are clearly not
42 being met. More recent increase in deforestation rate remains to be assessed. NYDF confirms that the
43 initiative did not reach its zero-deforestation goal (NYDF Assessment Partners 2020).

44 In 2010, the parties to the CBD adopted the Strategic Plan for Biodiversity 2011–2020 which included
45 20 targets known as the Aichi Biodiversity targets (Marques et al. 2014). Of relevance to the forestry
46 sector, Aichi Target 15 sets the goal of enhancing ecosystem resilience and the contribution of
47 biodiversity to carbon stocks through conservation and restoration, including ‘restoration of at least 15%
48 of degraded ecosystems’ (UNCBD 2010). The plan elaborates milestones, including the development

1 of national plans for potential restoration levels and contributions to biodiversity protection, carbon
2 sequestration, and climate adaptation to be integrated into other national strategies, including REDD+.
3 In 2020, however, the CBD found that while progress was evident for the majority of the Aichi
4 Biodiversity Targets, it was not sufficient for the achievement of the targets by 2020 (CBD 2020).

5 Recent efforts toward negative emissions through restoration include the Bonn Challenge, the African
6 Forest Landscape Restoration Initiative (AFR 100) and Initiative 20X20. The Bonn Challenge, initiated
7 in 2011 by the Government of Germany and the IUCN, is intended to catalyse the existing international
8 AFOLU commitments. It aims to bring 150 million hectares (Mha) of the world's deforested and
9 degraded land into restoration by 2020, and 350 Mha by 2030. AFR has the goal of restoring 100 Mha
10 specifically in Africa (AUDA-NEPAD 2019), while 20X20 aims to restore 20 Mha in Latin America
11 and the Caribbean (Anderson and Peimbert 2019). Increasing commitments for restoration have created
12 momentum for restoration interventions (Chazdon et al. 2017; Mansourian et al. 2017; Djenontin et al.
13 2018). To date 97 Mha has been pledged in NDCs. Yet only a small part of this goal has been achieved.
14 The Bonn Challenge Barometer – a progress-tracking framework and tool to support pledgers - indicates
15 that 27 Mha (InfoFLR 2018) are currently being restored, equivalent to 1.379 GtCO₂eq sequestered
16 (Dave et al. 2019). A key challenge in scaling up restoration has been to mobilise sufficient financing
17 (Liagre et al. 2015; Djenontin et al. 2018). This underscores the importance of building international
18 financing for restoration (equivalent to the Forest Carbon Partnership Facility focused on avoided
19 deforestation and degradation).

20 In sum, existing international agreements have had a small impact on reducing emissions from the
21 AFOLU sector and some success in achieving the enhancement of sinks through restoration. However,
22 these outcomes are nowhere near levels required to meet the Paris Agreement temperature goal –which
23 would require turning land use and forests globally from a net anthropogenic source during 1990-2010
24 to a net sink of carbon by 2030, and providing a quarter of emission reductions planned by countries
25 (Grassi et al. 2017). The AFOLU sector has so far contributed only modestly to net mitigation (see
26 Chapter 7).

27 **14.5.2.2 Energy sector**

28 International cooperation on issues of energy supply and security has a long and complicated history.
29 There exists a plethora of institutions, organisations, and agreements concerned with managing the
30 sector. There have been efforts to map the relevant actors, with authors in one case identifying six
31 primary organisations (Kérébel and Keppler 2009), in another sixteen (Lesage et al. 2010), and in a
32 third fifty (Sovacool and Florini 2012). At the same time, very little of that history has had climate
33 mitigation as its core focus. Global energy governance has encompassed five broad goals – security of
34 energy supply and demand, economic development, international security, environmental
35 sustainability, and domestic good governance – and as only one of these provides an entry point for
36 climate mitigation, effort in this direction has often been lost (van de Graaf and Colgan 2016). To take
37 one example, during the 1980s and 1990s a combination of bilateral development support and lending
38 practices from multilateral development banks pushed developing countries to adopt power market
39 reforms consistent with the Washington Consensus: towards liberalised power markets and away from
40 state-owned monopolies. The goals of these reforms did not include an environmental component, and
41 among the results was new investment in fossil-fired thermal power generation (Foster and Rana 2020).

42 As Goldthau and Witte (2010) document, the majority of governance efforts, outside of oil and gas
43 producing states, was oriented towards ensuring reliable and affordable access for oil and gas imports.
44 For example, the original rationale for the creation of the International Energy Agency (IEA), during
45 the oil crisis of 1973-74, was to manage a mechanism to ensure importing countries' access to oil (van
46 de Graaf and Lesage 2009). On the other side of the aisle, oil exporting countries created the
47 international institution of OPEC to enable them to influence oil output, thereby stabilising prices and
48 revenues for exporting countries (Fattouh and Mahadeva 2013). For years, energy governance was seen

1 as a zero-sum game between these poles (Goldthau and Witte 2010). The only international governance
2 agency focusing on low carbon energy sources was the International Atomic Energy Agency, with a
3 dual mission of promoting nuclear energy and nuclear weapons non-proliferation (Scheinman 1987).

4 More recently, however, new institutions have emerged, and existing institutions have realigned their
5 missions, in order to promote capacity building and global investment in low carbon energy
6 technologies. Collectively, these developments may support the emergence of a nascent field of global
7 sustainable energy governance, in which a broad range of global, regional, national, sub-national and
8 non-state actors, in aggregate, shape, direct and implement the low carbon transition through climate
9 change mitigation activities, which produce concomitant societal benefits (Bruce 2018). Beginning in
10 the 1990s, for example, the IEA began to broaden its mission from one concerned primarily with
11 security of oil supplies, which encompassed conservation of energy resources, to one also concerned
12 with the sustainability of energy use, including work programs on energy efficiency and clean energy
13 technologies and scenarios (van de Graaf and Lesage 2009). Scholars have suggested that it was the
14 widespread perception that the IEA was primarily interested in promoting the continued use of fossil
15 fuels, and underplaying the potential role of renewable technologies, that led a number of IEA member
16 states to successfully push for the creation of a parallel organisation, the International Renewable
17 Energy Agency (IRENA), which was then established in 2009 (van de Graaf 2013). An assessment of
18 IRENA's activities in 2015 suggested that the agency has a positive effect related to three core activities:
19 offering advisory services to member states regarding renewable energy technologies and systems;
20 serving as a focal point for data and analysis for renewable energy; and, mobilising other international
21 institutions, such as multilateral development banks, promoting renewable energy (Urpelainen and Van
22 de Graaf 2015). The United Nations, including its various agencies such as the Committee on
23 Sustainable Energy within the United Nations Economic Commission for Europe, has also played a role
24 in the realignment of global energy governance towards mitigation efforts. As a precursor to SDG 7,
25 the United Nations initiated in 2011 the *Sustainable Energy for All* initiative, which in addition to
26 aiming for universal access to modern energy services, included the goals of doubling the rate of
27 improvement in energy efficiency, and doubling by 2030 the share of renewable energy in the global
28 energy mix (Bruce 2018).

29 Sub-global agreements have also started to emerge, examples of issue-specific climate clubs. In 2015,
30 seventy solar-rich countries signed a framework agreement dedicated towards promoting solar energy
31 development (ISA 2015). In 2017 the Powering Past Coal Alliance was formed, uniting a set of states,
32 businesses, and non-governmental organisations around the goal of eliminating coal-fired power
33 generation by 2050 (Jewell et al. 2019; Blondeel et al. 2020). Scholars have argued that greater attention
34 to supply-side agreements such as this – focusing on reducing and ultimately eliminating the supply of
35 carbon-intensive energy sources – would strengthen the UNFCCC and Paris Agreement (Collier and
36 Venables 2014; Piggot et al. 2018; Asheim et al. 2019; Newell and Simms 2020). Chapter 6 of this
37 report, on energy systems, notes the importance of regional cooperation on electric grid development,
38 seen as necessary to enable higher shares of solar and wind power penetration (RGI 2011). Finally, a
39 number of transnational organisations and activities have emerged, such as *REN21*, a global community
40 of renewable energy experts (REN21 2019), and *RE100*, an NGO led initiative to enlist multilateral
41 companies to shift towards 100% renewable energy in their value chains (RE100 2019).

42 Whether a result of the above activities or not, multilateral development banks' lending practices have
43 shifted in the direction of renewable energy (Delina 2017), a point also raised in Chapter 15 of this
44 Assessment Report. Activities include new sources of project finance, concessional loans, as well as
45 loan guarantees, the latter through the Multilateral Investment Guarantee Agency (Multilateral
46 Investment Guarantee Agency 2019). This appears to matter. For example, Frisari and Stadelmann
47 (2015) find concessional lending by multilateral development banks to solar energy projects in Morocco
48 and India to have reduced overall project costs, due to more attractive financing conditions from

1 additional lenders, as well as reducing the costs to local governments. Labordena et al. (2017) projected
2 these results into the future, and found that with the drop in financing costs, renewable energy projects
3 serving all major demand centres in sub-Saharan Africa could reach cost parity with fossil fuels by
4 2025, whereas without the drop in financing costs associated with concessional lending, this would not
5 be the case. Similarly, Creutzig et al. (2017) suggest that greater international attention to finance could
6 be instrumental in the full development of solar energy.

7 Despite improvements in the international governance of energy, it still appears that a great deal of this
8 is still concerned with promoting further development of fossil fuels. One aspect of this is the
9 development of international legal norms. A large number of bilateral and multilateral agreements,
10 including the 1994 Energy Charter Treaty, include provisions for using a system of investor-state
11 dispute settlement (ISDS) designed to protect the interests of investors in energy projects from national
12 policies that could lead their assets to be stranded. Numerous scholars have pointed to ISDS being able
13 to be used by fossil-fuel companies to block national legislation aimed at phasing out the use of their
14 assets (Bos and Gupta 2019; Tienhaara 2018). Another aspect is finance; Gallagher et al. (2018)
15 examine the role of national development finance systems, focusing in particular on China. While there
16 has been a great deal of finance devoted to renewable energy, they find the majority of finance devoted
17 to projects associated either with fossil fuel extraction or with fossil fuel-fired power generation.
18 Ascensão et al. (2018) similarly suggest that activities associated with the Belt and Road Initiative could
19 play a role in slowing down mitigation efforts in developing countries.

20 Given the complexity of global energy governance, it is impossible to make a definitive statement about
21 its overall contribution to mitigation efforts. Three statements, do however, appear to be robust. First,
22 prior to the emergence of climate change on the global political agenda, international cooperation in the
23 area of energy was primarily aimed at expanding and protecting the use of fossil energy, and these goals
24 were entrenched in a number of multilateral organisations. Second, since the 1990s, international
25 cooperation has gradually taken climate mitigation on board as one of its goals, seeing a realignment of
26 many pre-existing organisations priorities, and the formation of a number of new international
27 arrangements oriented towards the development renewable energy resources. Third, the realignment is
28 far from complete, and there are still examples of international cooperation having a chilling effect on
29 climate mitigation, particularly through financing and investment practices, including legal norms
30 designed to protect the interests of owners of fossil assets.

31 **14.5.2.3 Transportation**

32 The transportation sector has been a particular focus of cooperative efforts on climate mitigation that
33 extend beyond the sphere of the UNFCCC climate regime. A number of these cooperative efforts
34 involve transnational public-private partnerships, such as the European-based Transport
35 Decarbonisation Alliance, which brings together countries, regions, cities and companies working
36 towards the goal of a ‘net-zero emission mobility system before 2050’ (TDA 2019). Other efforts are
37 centred in specialised UN agencies, such as the International Civil Aviation Organisation (ICAO) and
38 the International Maritime Organisation (IMO).

39 Measures introduced by the ICAO and IMO have addressed CO₂ emissions from international shipping
40 and aviation. Emissions from these parts of the transportation sector are generally excluded from
41 national emissions reduction policies and NDCs because the ‘international’ location of emissions
42 release makes allocation to individual nations difficult (Bows-Larkin 2015; Lyle 2018; Hoch et al.
43 2019). The measures adopted by ICAO take the form of standards and recommended practices that are
44 adopted in national legislation. IMO publishes ‘regulations’ but does not have a power of enforcement,
45 with non-compliance a responsibility of flag states that issue a ship’s ‘MARPOL’ certificate.

46 As discussed in Chapter 2 and Figure SPM.4, international aviation currently accounts for
47 approximately 1% of global GHG emissions, with international shipping contributing 1.2% of global
48 GHG emissions. These international transport emissions are projected to be between approximately 60-

1 220% of global emissions of CO₂ in 2050, as represented by the four main illustrative model pathways
2 in SR1.5 (Rogelj et al. 2018; UNEP 2020) Notably, however, the climate impact of aviation emissions
3 is estimated to be 2-4 times higher due to non-CO₂ effects (Terrenoire et al. 2019; Lee et al. 2021a).
4 Increases in trans-Arctic shipping and tourism activities with sea ice loss are also forecast to have strong
5 regional effects due to ships' gas and particulate emissions (Stephenson et al. 2018).

6 The Kyoto Protocol required Annex I parties to pursue emissions reductions from aviation and marine
7 bunker fuels by working through IMO and ICAO (UNFCCC 1997, Art. 2.2). Limited progress was
8 made by these organisations on emissions controls in the ensuing decades (Liu 2011b), but greater
9 action was prompted by conclusion of the SDGs and Paris Agreement (Martinez Romera 2016),
10 together with unilateral action, such as the EU's inclusion of aviation emissions in its Emissions Trading
11 Scheme (ETS) (Dobson 2020).

12 The Paris Agreement neither explicitly addresses emissions from international aviation and shipping,
13 nor repeats the Kyoto Protocol's provision requiring parties to work through ICAO/IMO to address
14 these emissions (Hoch et al. 2019). This leaves unclear the status of the Kyoto Protocol's article 2.2
15 directive after 2020 (Martinez Romera 2016; Dobson 2020), potentially opening up scope for more
16 attention to aviation and shipping emissions under the Paris Agreement (Doelle and Chircop 2019).
17 Some commentators have suggested that emissions from international aviation and shipping should be
18 part of the Paris Agreement (Gençsü and Hino 2015; Traut et al. 2018), and shipping and aviation
19 industries themselves may prefer emissions to be treated under an international regime rather than a
20 nationally-oriented one (Gilbert and Bows 2012). In the case of shipping emissions, there is nothing in
21 the Paris Agreement to prevent a party from including international shipping in some form in its NDC
22 (Doelle and Chircop 2019) Under the Paris Rulebook, parties "should report international aviation and
23 marine bunker fuel emissions as two separate entries and should not include such emissions in national
24 totals but report them distinctly, if disaggregated data are available" (UNFCCC 2019d).

25 ICAO has an overarching climate goal to "limit or reduce the impact of aviation greenhouse gas
26 emissions on the global climate" with respect to international aviation. In order to achieve this, ICAO
27 has two global aspirational goals for the international aviation sector, of 2% annual fuel efficiency
28 improvement through 2050 and carbon neutral growth from 2020 onwards (ICAO 2016). In order to
29 achieve these global aspirational goals, ICAO is pursuing a 'basket' of mitigation measures for the
30 aviation sector consisting of technical and operational measures, such as a CO₂ emissions standard for
31 new aircraft adopted in 2016, measures on sustainable alternative fuels and a market-based measure,
32 known as the Carbon Offset and Reduction Scheme for International Aviation (CORSIA), which the
33 triennial ICAO Assembly of 193 Member States resolved to establish in 2016 (ICAO 2016). In line
34 with the 2016 ICAO Assembly Resolution that established CORSIA, in mid-2018, the ICAO's 36-
35 member state governing Council adopted a series of Standards and Recommended Practices (SARPs),
36 now contained in Annex 16, Volume IV of the Chicago Convention (1944), as a common basis for
37 CORSIA's implementation and enforcement by each state and its aeroplane operators. From 1 January
38 2019, the CORSIA SARPs require states and their operators to undertake an annual process of
39 monitoring, verification, and reporting of emissions from all international flights, including to establish
40 CORSIA's emissions baseline (ICAO 2019).

41 Based on this emissions data, CORSIA's carbon offsetting obligations commence in 2021, with 3-year
42 compliance cycles, including a pilot phase in 2021-2023. States have the option to participate in the
43 pilot phase and the subsequent voluntary 3-year cycle in 2024-2026. CORSIA becomes mandatory from
44 2027 onwards for states whose share in the total international revenue tonnes per kilometre (RTK) is
45 above a certain threshold (Hoch et al. 2019). Under CORSIA, aviation CO₂ emissions are not capped,
46 but rather emissions that exceed the CORSIA baseline are compensated through use of 'offset units'
47 from emissions reduction projects in other industries (Erling 2018). However, it is unclear whether the
48 goal of carbon neutral growth and further CO₂ emissions reduction in the sector will be sufficiently

1 incentivised solely through the use of such offsets in combination with ICAO's manufacturing
2 standards, programs, and state action plans, without additional measures being taken, for example,
3 constraints on demand (Lyle 2018). If countries such as China, Brazil, India and Russia do not
4 participate in CORSIA's voluntary offsetting requirements this could significantly undermine its
5 capacity to deliver fully on the sectoral goal by limiting coverage of the scheme to less than 50% of
6 international aviation CO₂ emissions in the period 2021-2026 (Climate Action Tracker 2020b; Hoch et
7 al. 2019). In addition, a wide range of offsets are approved as 'eligible emissions units' in CORSIA,
8 including several certified under voluntary carbon offset schemes, which may go beyond those
9 eventually agreed under the Paris Agreement Article 6 mechanism (Hoch et al. 2019). It is noted,
10 however, that ICAO applies a set of 'Emissions Unit Eligibility Criteria' agreed in March 2019, which
11 specify required design elements for eligible programs. In June 2020, the ICAO Council decided to
12 define 2019 emissions levels, rather than an average of 2019 and 2020 emissions, as the baseline year
13 for at least the first three years of CORSIA, although there were significant reductions (45-60%) in
14 aviation CO₂ emissions in 2020 compared with 2019 as a result of reductions in air travel associated
15 with the COVID-19 pandemic (Climate Action Tracker 2020b).

16 Other measures adopted by ICAO include an aircraft CO₂ emissions standard that applies to new aircraft
17 type designs from 2020, and to aircraft type designs already in production as of 2023 (Smith and Ahmad
18 2018). Overall, CORSIA and regional measures, such as the EU ETS, are estimated to reduce aviation
19 carbon emissions by only 0.8% per year from 2017-2030 (noting, however, that 'if non-CO₂ emissions
20 are included in the analysis, then emissions will increase') (Larsson et al. 2019). Accordingly, pathways
21 consistent with the temperature goal of the Paris Agreement are likely to require more stringent
22 international measures for the aviation sector (Larsson et al. 2019).

23 Similar to ICAO, the IMO has a stated vision of remaining committed to reducing greenhouse gas
24 emissions from international shipping and, as a matter of urgency, aims to phase them out as soon as
25 possible in this century. IMO has considered a range of measures to monitor and reduce shipping
26 emissions. In 2016, the IMO's Marine Environment Protection Committee (MEPC) approved an
27 amendment to the MARPOL Convention Annex VI for the introduction of a Mandatory Global Data
28 Collection scheme for fuel oil consumption of ships (Dobson 2020). Other IMO measures have focused
29 on energy efficiency (Martinez Romera 2016). The IMO's Energy Efficiency Design Index (EEDI),
30 which is mandatory for new ships, is intended, over a ten-year period, to improve energy efficiency by
31 up to 30% in several categories of ships propelled by diesel engines (Smith and Ahmad 2018). In May
32 2019, the MEPC approved draft amendments to the MARPOL Convention Annex VI, which if adopted,
33 will bring forward the entry into force of the third phase of the EEDI requirements to 2022 instead of
34 2025 (IMO 2019; Joung et al. 2020).

35 However, it is unlikely that the EEDI and other IMO technical and operational measures will be
36 sufficient to produce 'the necessary emissions reduction because of the future growth in international
37 seaborne trade and world population' (Shi and Gullett 2018). Consequently, in 2018, the IMO adopted
38 an initial strategy on reduction of GHG emissions from ships (IMO 2018). This includes a goal for
39 declining carbon intensity of the sector by reducing CO₂ emissions per transport work, as an average
40 across international shipping, by at least 40% by 2030, and pursuing efforts towards 70% by 2050,
41 compared to 2008 levels (IMO 2018, para. 3.1). The strategy also aims for peaking of total annual GHG
42 emissions from international shipping as soon as possible and a reduction by at least 50% by 2050
43 compared to 2008 levels, whilst pursuing efforts towards phasing them out 'as soon as possible in this
44 century' as a point 'on a pathway of CO₂ emissions reduction consistent with the Paris Agreement
45 temperature goals' (IMO 2018, para. 2, 3.1). The shipping industry is on track to overachieve the 2030
46 carbon intensity target but not its 2050 target (Climate Action Tracker 2020c). The initial IMO strategy
47 is to be kept under review by the MEPC with a view to adoption of a revised strategy in 2023.

1 The IMO's initial strategy identifies a series of candidate short-term (2018-2023), medium-term (2023-
2 2030) and long-term (beyond 2030) measures for achieving its emissions reduction goals, including
3 possible market-based measures in the medium-to-long term (IMO 2018, paras. 4.7-4.9). Further
4 progress on market-based measures faces difficulty in light of conflicts between the CBDRRC principle
5 of the climate regime and the traditional non-discrimination approach and principle of no more
6 favourable treatment enshrined in MARPOL and other IMO conventions (Zhang 2016). Both the
7 CBDRRC and non-discrimination principles are designated as 'principles guiding the initial strategy'
8 (IMO 2018, para. 3.2). The challenges encountered in introducing global market-based measures for
9 shipping emissions under the IMO have prompted regional initiatives such as the proposed extension
10 of the EU ETS to emissions from maritime activities (Christodoulou et al. 2021), which was announced
11 on 14 July 2021 by the EU Commission as part of its 'Fit for 55' legislative package (European
12 Commission 2021).

13 While the IMO strategy is viewed as a reasonable first step that is ambitious for the shipping industry,
14 achieving the 'vision' of alignment with the temperature goals of the Paris Agreement requires concrete
15 implementation measures and strengthened targets in the next iteration in 2023 (Doelle and Chircop
16 2019; Climate Action Tracker 2020c). As a step towards this, in 2020, the IMO's MEPC put forward
17 draft amendments to the MARPOL convention that would require ships to combine a technical and an
18 operational approach to reduce their carbon intensity. These amendments were formally adopted by the
19 Committee at its session in June 2021.

20

21 **14.5.3 Civil society and social movements**

22 Transnationally organised civil society actors have had long-standing involvement in international
23 climate policy, with a particular focus on consulting or knowledge-sharing where they are present in
24 transnational climate governance initiatives (Michaelowa and Michaelowa 2017). The term 'civil
25 society' generally denotes 'the voluntary association of individuals in the public sphere beyond the
26 realms of the state, the market and the family' (de Bakker et al. 2013, p. 575). Whereas civil society
27 organisations are usually involved in lobbying or advocacy activities in a public arena, social
28 movements focus on mobilisation and action for social change (Daniel and Neubert 2019). Examples
29 of civil society groups involved in international climate policy include non-governmental organisations
30 (NGOs) such as Greenpeace International, the World Wide Fund for Nature, the Environmental
31 Defence Fund, the World Resources Institute, Friends of the Earth and Earthjustice among many others,
32 as well as NGO networks such as the Climate Action Network (CAN), which has over 1300 NGO
33 members in more than 130 countries, working to promote government and individual action to limit
34 human-induced climate change to ecologically sustainable levels (Climate Action Network
35 International 2020). The influence of civil society engagement in global climate governance is well-
36 acknowledged, with these organisations' globally dispersed constituencies and non-state status offering
37 perspectives that differ in significant ways from those of many negotiating states (Derman 2014).

38 Historically, the issue of climate change did not give rise to intense, organised transnational protest
39 characteristic of social movements (McAdam 2017). During the 1990s and early 2000s, the activities
40 of the global climate movement were concentrated in developed countries and largely sought to exercise
41 influence through participation in UNFCCC COPs and side events (Almeida 2019). The mid-2000s
42 onwards, however, saw the beginnings of use of more non-institutionalised tactics, such as simultaneous
43 demonstrations across several countries, focusing on a grassroots call for climate justice that grew out
44 of previous environmental justice movements (Almeida 2019). Groups representing Indigenous, youth,
45 women, and labour rights brought to the fore new tools of contention and new issues in the UNFCCC,
46 such as questions of a just transition and gender equity (Allan 2020).

1 Climate justice has been variously defined, but centres on addressing the disproportionate impacts of
2 climate change on the most vulnerable populations and calls for community sovereignty and functioning
3 (Schlosberg and Collins 2014; Tramel 2016). Contemporary climate justice groups mobilise multiple
4 strands of environmental justice movements from the Global North and South, as well as from distinct
5 indigenous rights and peasant rights movements, and are organised as a decentralised network of
6 semiautonomous, coordinated units (Claeys and Delgado Pugley 2017; Tormos-Aponte and García-
7 López 2018). The climate justice movement held global days of protest in most of the world's countries
8 in 2014 and 2015, and mobilised another large campaign in 2018 (Almeida 2019). The polycentric
9 arrangement of the global climate movement allows simultaneous influence on multiple sites of climate
10 governance, from the local to the global levels (Tormos-Aponte and García-López 2018).

11 Prominent examples of new climate social movements that operate transnationally are Extinction
12 Rebellion and Fridays for Future, which collectively held hundreds of coordinated protests across the
13 globe in 2019-2021, marking out 'the transnational climate justice movement as one of the most
14 extensive social movements on the planet' (Almeida 2019). Fridays for Future is a children's and youth
15 movement that began in August 2018, inspired by the actions of then 15-year old Greta Thunberg who
16 pledged to strike in front of the Swedish parliament every Friday to protest against a lack of action on
17 climate change in line with the Paris Agreement targets (Fridays for Future 2019). Fridays for Future
18 events worldwide encompass more than 200 countries and millions of strikers. The movement is
19 unusual for its focus on children and the rights of future generations, with children's resistance having
20 received little previous attention in the literature. Fridays for the Future is regarded as a progressive
21 resistance movement that has quickly achieved global prominence (for example, Thunberg was invited
22 to address governments at the UN Climate Summit in New York in September 2019) and is credited
23 with helping to support the discourse about the responsibility of humanity as a whole for climate change
24 (Holmberg and Alvinus 2019). Whereas Fridays for Future has focused on periodic protest action,
25 Extinction Rebellion has pursued a campaign based on sustained non-violent direct citizen action that
26 is focused on three key demands: declaration of a 'climate emergency', acting now to halt biodiversity
27 loss and reduce greenhouse gas emissions to net zero by 2025, and creation of a citizen's assembly on
28 climate and ecological justice (Booth 2019; Extinction Rebellion 2019). The movement first arose in
29 the United Kingdom (UK) – where it claimed credit for adoption of a climate emergency declaration
30 by the UK government – but now has a presence in 45 countries with some 650 groups having formed
31 globally (Gunningham 2019).

32 The Paris Agreement's preamble explicitly recognises the importance of engaging "various actors" in
33 addressing climate change, and the decision adopting the Agreement created the Non-State Actor Zone
34 for Climate Action platform to aid in scaling up these efforts. Specific initiatives have also been taken
35 to facilitate participation of particular groups, such as the UNFCCC's Local Communities and
36 Indigenous Peoples Platform, which commenced work in Katowice in 2019. Climate movements based
37 in the Global South, as well as in Indigenous territories, are playing an increasingly important role in
38 transnational negotiations through networks such as the Indigenous Peoples Platform. These groups
39 highlight the voices and perspectives of communities and peoples particularly affected by climate
40 change. For instance, the Pacific Climate Warriors is a grassroots network of young people from various
41 countries in the Pacific Islands region whose activities focus on resisting narratives of future
42 inevitability of their Pacific homelands disappearing, and re-envisioning islanders as warriors defending
43 rights to homeland and culture (McNamara and Farbotko 2017). Youth global climate activism,
44 particularly involving young Indigenous climate activists, is another notable recent development.
45 Although there remains little published literature on Indigenous youth climate activism (MacKay et al.
46 2020), analysis of online sources indicates the emergence of several such groups, including the Pacific
47 Climate Warriors and Te Ara Whatu from Aotearoa New Zealand (Ritchie 2021), as well as Seed Mob
48 in Australia.

1 Transnational civil society organisations advocating for climate justice in global governance have
2 articulated policy positions around rights protections, responsibility-based approaches to climate
3 finance, and the need for transparency and accountability (Derman 2014). Another recent area of
4 activity, which overlaps with that of emerging investor alliances (discussed further in Section 14.5.4),
5 is the sustainability of capital investment in fossil fuel assets. Efforts to shift away from fossil fuels led
6 by civil society include the Beyond Coal Campaign (in the US and Europe) and the organisation for a
7 Fossil Fuel Non-proliferation Treaty. 350.org has supported mobilisation of youth and university
8 students around a campaign of divestment that has grown into a global movement (Gunningham 2019).
9 As Mormann (2020) notes, as of November 2020 ‘more than 1,200 institutional investors managing
10 over USD14 trillion of assets around the world have committed to divest some or all of their fossil fuel
11 holdings’ (Mormann 2020). Studies suggest that the direct impacts of the divestment movement have
12 so far been small, given a failure to differentiate between different types of fossil fuel companies, a lack
13 of engagement with retail investors, and a lack of guidance for investors on clean energy re-investment
14 (Osofsky et al. 2019; Mormann 2020). The movement has had a more significant impact on public
15 discourse by raising the profile of climate change as a financial risk for investors (Bergman 2018).
16 Blondeel et al. (2019) also find that broader appeal of the divestment norm was achieved when moral
17 arguments were linked to financial ones, through the advocacy of economic actors, such as Bank of
18 England’s governor.

19 Climate justice campaigns by transnational civil society organisations increasingly embrace action
20 through the courts. Chapter 13 discusses the growth and policy impact of such ‘climate litigation’
21 brought by civil society actors in domestic courts, which is attracting increasing attention in the
22 literature (Setzer and Vanhala 2019; Peel and Osofsky 2020). Transnational and international court
23 actions focused on climate change, by contrast, have been relatively few in number (Peel and Lin 2019).
24 This reflects—at least in part—the procedural hurdles to bringing such claims, as in many international
25 courts and tribunals (outside of the area of human rights or investor-state arbitration) litigation can only
26 be brought by states (Bruce 2017). However, there have been active discussions about seeking an
27 advisory opinion from the International Court of Justice (ICJ) on states’ international obligations
28 regarding the reduction of greenhouse gas emissions (Sands 2016; Wewerinke-Singh and Salili 2020),
29 or bringing a case to the International Tribunal for the Law of the Sea on marine pollution harms caused
30 by climate change (Boyle 2019). In September 2021 the Government of Vanuatu announced a campaign
31 to seek an advisory opinion from the ICJ. The aim of climate litigation more generally is to supplement
32 other regulatory efforts by filling gaps and ensuring that interpretations of laws and policies are aligned
33 with climate mitigation goals (Osofsky 2010).

34 The overall impact of transnationally-organised civil society action and social movements for
35 international cooperation on climate change mitigation has not been comprehensively evaluated in the
36 literature. This may reflect the polycentric organisation of the movement, which poses challenges for
37 coordinating between groups operating in different contexts, acting with different strategies and around
38 multiple issues, and lobbying multiple decision-making bodies at various levels of government in a
39 sustainable way (Tormos-Aponte and García-López 2018). There is some literature emerging on
40 environmental defenders and their need for protection against violence and repression, particularly in
41 the case of Indigenous environmental defenders who face significantly higher rates of violence
42 (Scheidel et al. 2020). Scheidel et al. (2020) also find that combining strategies of preventive
43 mobilisation, protest diversification and litigation can enhance rates of success for environmental
44 defenders in halting environmentally destructive projects. In the area of climate litigation,
45 commentators have noted the potential for activists and even researchers to suffer retaliation through
46 the courts as a result of “strategic lawsuits against public participation” (SLAPP) and lawsuits against
47 researchers brought by fossil fuel interests (Setzer and Byrnes 2019; Setzer and Benjamin 2020).
48 Influence of social movements may be enhanced through taking advantage of ‘movement spillover’
49 (the involvement of activists in more than one movement) (Hadden 2014) and coordination of activities

1 with a range of ‘non-state governors,’ including cities, sub-national governments, and investor groups
2 (Gunningham 2019). Studies of general societal change suggest that once 3.5% of the population are
3 mobilised on an issue, far-reaching change becomes possible (Gladwell 2002; Chenoweth and
4 Belgioioso 2019) – a tipping point that may be approaching in the case of climate change (Gunningham
5 2019). As noted in Chapter 5, in the particular case of low-carbon technologies, ‘if 10-30% of the
6 population were to demonstrate commitment to low-carbon technologies, behaviours, and lifestyles,
7 new social norms would be established.’

9 **14.5.4 Transnational business and public-private partnerships and initiatives**

10 Combined national climate commitments fall far short of the Paris Agreement's long term temperature
11 goals. Similar political ambition gaps persist across various areas of sustainable development. Many
12 therefore argue that actions by nonstate actors, such as businesses and investors, cities and regions, and
13 nongovernmental organizations (NGOs), are crucial. However, nonstate climate and sustainability
14 actions may not be self-reinforcing but may heavily depend on supporting mechanisms. Governance
15 risk-reduction strategies can be combined to maximize nonstate potential in sustainable and climate-
16 resilient transformations (Chan et al. 2019).

17 An important feature of the evolving international climate policy landscape of the recent years is the
18 entrepreneurship of UN agencies such as UNEP and UNDP, as well as international organizations such
19 as the World Bank in initiating public-private partnerships (PPPs). Andonova (2017) calls this
20 ‘governance entrepreneurship’. Such partnerships can be defined as ‘voluntary agreements between
21 public actors (IOs, states, or sub-state public authorities) and non-state actors (non-governmental
22 organizations (NGOs), companies, foundations, etc.) on a set of governance objectives and norms, rules,
23 practices, and/or implementation procedures and their attainment across multiple jurisdictions and
24 levels of governance’ (Andonova 2017). Partnerships may carry out different main functions: first,
25 *policy development*, establishing new agreements on norms, rules, or standards among a broader set of
26 governmental and non-governmental actors; second, *enabling implementation and delivery of services*,
27 by combining resources from governmental and non-governmental actors; and, third, *knowledge*
28 *production and dissemination*, to e.g. the evolution of relevant public policies.

29 An example of a prominent PPP in the area of climate mitigation is the Renewable Energy Network
30 (REN21 2019), which is a global multi-stakeholder network focused on promoting renewable energy
31 policies in support of the transition to renewable energy through knowledge, established 2004. It
32 includes members from industry, NGOs, intergovernmental organizations, and science and academia.
33 Another example is the Green Economy Coalition founded in 2009 to bring to bear the perspectives of
34 workers, business, poor people, the environment community, and academics in the transition to greener
35 and more sustainable economy. Another example is that in 2015 Peru in collaboration with France and
36 the UNFCCC Secretariat launched the ‘Non-State Actor Zone for Climate Action’ (NAZCA), an online
37 platform to showcase commitments to climate action by companies, cities, regions and investors (Chan
38 et al. 2016; Bertoldi et al. 2018). More recently, the UNFCCC ‘Race to Zero’ initiative led by High-
39 level Climate Champions Nigel Topping and Gonzalo Muñoz seeks to mobilize actors beyond national
40 governments to join the Climate Ambition Alliance and pursue net zero CO₂ targets. Its membership
41 includes 454 cities, 23 regions, 1,391 businesses, 74 of the biggest investors, and 569 universities.

42 PPPs may also be developed to assist with implementation and support of states’ climate mitigation
43 commitments. For instance, UNEP has initiated a number of PPPs for climate change finance. These
44 are designed to increase financing for the purposes of disseminating low-carbon technologies to tackle
45 climate change and promote clean energy in many parts of developing countries (UNEP 2018b;
46 Charlery and Traerup 2019).

1 In the same vein, in 2010 FAO delivered the Framework for Assessing and Monitoring Forest
2 Governance. The Framework draws on several approaches currently in use or under development in
3 major forest governance-related processes and initiatives, including the World Bank's Framework for
4 Forest Governance Reform. The Framework builds on the understanding that governance is both the
5 context and the product of the interaction of a range of actors and stakeholders with diverse interests
6 (FAO 2010). For example, UNFCCC and UN-REDD program focus on REDD+ and UNEP focus on
7 TEEB (a global initiative focusing on the economics of ecosystems and biodiversity) institutional
8 mechanisms have been conceptualized as a 'win-win-win' for mitigating climate, protecting
9 biodiversity and conserving indigenous culture by institutionalizing payments on carbon sequestration
10 and biodiversity conservation values of ecosystems services from global to local communities. These
11 mechanisms include public-private partnership, and non-governmental organization participation.
12 REDD+ and TEEB allocation policies will be interventions in a highly complex system, and will
13 inevitably involve trade-offs; therefore, it is important to question the 'win-win-win' discourse (Zia and
14 Kauffman 2018; Goulder et al. 2019). The initial investment and the longer periods of recovery of
15 investment are sometimes barriers to private investment. In this sense, it is important to have
16 government incentives and encourage public-private investment (Ivanova and Lopez 2013).

17
18 The World Bank has also established several partnerships since 2010, mainly in the field of carbon
19 pricing. Prominent examples are the Networked Carbon Markets initiative (established 2013; spanning
20 both governmental actors and experts; now entering a phase II) and the Carbon Pricing Leadership
21 Coalition, established in 2015 and spanning a wide range of governmental and non-governmental
22 actors, not least within business (World Bank 2018, 2019; Wettestad et al. 2021). These partnerships
23 deal with knowledge production and dissemination and seek to enable implementation of carbon pricing
24 policies. The leadership role of the international 'heavyweight' World Bank gives these partnerships
25 additional comparative political weight, meaning also a potentially greater involvement of powerful
26 finance ministries/ministers generally involved in Bank matters and meetings.

27 PPPs for cooperation on climate mitigation goals have emerged at multiple levels of governance beyond
28 the realm of international organizations. For example, PPP funding for cities expanded rapidly in the
29 1990s and outpaced official external assistance almost tenfold. Most of the PPP infrastructure
30 investment has been aimed at telecommunications, followed by energy. However, with the exception
31 of the telecommunications sector, PPP investments have generally bypassed low-income countries
32 (Ivanova 2017). It is therefore not surprising that PPPs have added relatively little to the financing of
33 urban capital in developing countries over the past two decades (Bahl and Linn 2014). Liu and Waibel
34 (2010) argue that the inherent risk of urban investment is the main obstacle to increasing the flow of
35 private capital. Nevertheless, there have been cases where PPP investments have exceeded official
36 external aid flows even for water and sanitation, and highly visible projects have been funded with PPPs
37 in selected metropolitan areas of developing countries, including urban rail projects in Bangkok, Kuala
38 Lumpur, and Manila (Liu and Waibel 2010).

39 Local governments are also creating cross-sector social partnerships (CSSPs) at the sub-national level;
40 entities created for addressing social, economic, and/or environmental issues with partner organizations
41 from the public, private and civil society sectors (Crane and Seitanidi 2014). In particular, with support
42 from international networks such as ICLEI Local Governments for Sustainability, C40, Global
43 Covenant of Mayors, and Global 100% Renewable Energy, local governments around the world are
44 committing to aggressive carbon reduction targets for their cities (Ivanova et al. 2015; Clarke and
45 Ordonez-Ponce 2017; Kona et al. 2018). Research on CSSPs implementing community sustainability
46 plans shows that climate change is one of the four most common issues, after waste, energy and water
47 (which are also highly relevant to climate mitigation) (MacDonald et al. 2017).

1 Community climate action plans consider all GHGs emitted within the local geographic boundaries,
2 including from industry, home heating, burning fuel in vehicles, etc. It is these community plans that
3 require large multi-stakeholder partnerships to be successful. Partners in these partnerships generally
4 include the local government departments, other government departments, utilities, large businesses,
5 Chamber of Commerce, some small and medium sized enterprises, universities, schools, and local civil
6 society groups (Clarke and MacDonald 2016). Research shows that the partnership's structural features
7 enable the achievement of plan outcomes, such as reducing GHG emissions, while also generating value
8 for the partners (Austin and Seitanidi 2012; Clarke and MacDonald 2016; Clarke and Ordonez-Ponce
9 2017). Stua (2017b) explores the Mitigation Alliances (MAs) on the national level. The internal
10 governance model of MAs consists of overarching authorities mandated to harmonize the overall
11 organizational structure. These authorities guarantee an effective, equitable and transparent functioning
12 of the MA's pillars (the demand, supply, and exchange of mitigation outcomes), in line with the
13 principles and criteria of the Paris Agreement. This hybrid governance model relies upon its unique
14 links with international climate institutions (Stua 2017a).

15 Transnational business partnerships are a growing feature of the landscape of multi-level, multi-actor
16 governance of climate change. Many business leaders embraced the ethos of "business cannot succeed
17 in societies that fail". Examples of this line of reasoning are: poverty limits consumer spending,
18 political instability disrupts business activity, and climate change threatens the production and
19 distribution of goods and services. Such situations endanger MNE investments, global asset
20 management funds, and the core business of international insurance companies and pension funds (van
21 Tulder et al. 2021).

22 A leading example is the World Business Council on Sustainable Development (WBCSD), a global,
23 CEO-led organization of over 200 leading businesses working together to accelerate the transition to a
24 sustainable world. Member companies come from all business sectors and all major economies,
25 representing a combined revenue of more than USD8.5 trillion and with 19 million employees. The
26 WBCSD aims to enhance 'the business case for sustainability through tools, services, models and
27 experiences'. It includes a Global Network of almost 70 national business councils across the globe.
28 The overall vision is to create a world where more than 9 billion people are all living well and within
29 the boundaries of our planet, by 2050. Vision 2050, released in 2010, explored what a sustainable world
30 would look like 2050, how such a world could be realized, and the role that business can play in making
31 that vision a reality. A few years later, Action2020 took that Vision and translated it into a roadmap of
32 necessary business actions and solutions (WBCSD 2019). WBCSD focuses on those areas where
33 business operates and can make an impact. They identify six transformation systems that are critical in
34 this regard: Circular Economy, Climate and Energy, Cities and Mobility, Food and Nature, People and
35 Redefining Value. All have an impact on climate. An important initiative launched in September of
36 2008 – the 'natural climate solutions', has the objective of leveraging business investment to capture
37 carbon out of the atmosphere. This initiative has built strong cross-sectoral partnerships and is intended
38 to tap into this immense emissions reduction solution potential through natural methods with the help
39 of private investment.

40 The Global Methane Initiative is a multilateral partnership launched in 2010 by the United States
41 Environmental Protection Agency along with thirty-six other countries to generate a voluntary, non-
42 binding agenda for global collaboration to decrease anthropogenic methane releases. The GMI builds
43 on the Methane to Market (M2M) Partnership, an international partnership launched in 2004. In addition
44 to the GMI's own financial assistance, the initiative receives financial backing from the Global Methane
45 Fund (GMF) for methane reduction projects. The GMF is a fund created by governments and private
46 donors (Leonard 2014).

47 Another potentially influential type of transnational business partnership is investor coalitions or
48 alliances formed for the purpose of pushing investee companies to adopt stronger measures for stranded

1 asset management and climate change mitigation. MacLeod & Park (2011, p. 55) argue that these
2 transnational groups ‘attempt to re-orient and “regulate” the behaviour of business by holding
3 corporations accountable via mechanisms of information sharing, monitoring of environmental impacts,
4 and disclosure of activities related to the corporate climate footprint’. This favours a theory of active
5 ownership (investor engagement with corporate boards) over capital divestment as the optimal pathway
6 to shape the behaviour of corporate actors on climate risk (Kruitwagen et al. 2017; Krueger et al. 2020).

7 Transnational cooperative action by investors on climate mitigation has been facilitated by international
8 standard-setting on issues of climate risk and disclosure. For example, in 2017 the Financial Stability
9 Board’s Taskforce on Climate-related Financial Disclosures (TCFD) adopted international
10 recommendations for climate risk disclosure (TCFD 2017). These recommendations, which apply to all
11 financial-sector organizations, including banks, insurance companies, asset managers, and asset owners,
12 have received strong support from investor coalitions globally, including Climate Action 100+ (with
13 300 investors with more than USD33 trillion in assets under management), the Global Investor
14 Coalition on Climate Change (a coalition of regional investor groups across Asia, Australia, Europe and
15 North America) and the Institutional Investors Group on Climate Change (IIGCC). One of the key
16 recommendations of the TCFD calls for stress-testing of investment portfolios taking into consideration
17 different climate-related scenarios, including a 2° C or lower scenario. Broad adoption of the TCFD
18 recommendations could provide a basis for decisions by investors to shift assets away from climate-
19 risk exposed assets such as fossil fuel extraction projects (Ososky et al. 2019). There is strong evidence
20 showing the urgent need for scaling-up climate finance to mitigate greenhouse gases in line with pursuit
21 of limiting the temperature increase to 1.5 °C above pre-industrial levels, and to support adaptation to
22 safeguard the international community from the consequences of a changing climate. While public
23 actors have a responsibility to deploy climate finance, it is clear that the contribution from the private
24 sector needs to be significant (Gardiner et al. 2016).

25 As most of these partnerships are of recent vintage an assessment of their effectiveness is premature.
26 Instead, partnerships can be assessed on the basis of the three main functions introduced earlier. Starting
27 with policy development, i.e. establishing new agreements on norms, rules, or standards among a
28 broader set of governmental and non-governmental actors, this is not the most prominent aspect of
29 partnerships so far, although both the cities’ networks and risk disclosure recommendations include
30 some elements of this. The second element, enabling implementation and delivery of services, by
31 combining resources from governmental and non-governmental actors, seems to be a more prominent
32 part of the partnerships (Ivanova et al. 2020). Both UNEP financing, the World Business Council on
33 Sustainable Development (WBCSD), the REDD+ and TEEB mechanisms, and PPP funding for cities
34 are examples here. Finally, the third element, knowledge production and dissemination, for example,
35 contributing to the evolution of relevant public policies, is the most prominent part of these partnerships,
36 with the majority including such activities.

37 There is a relatively large volume of literature that assesses PPPs in general. Much of this applies to
38 partnerships which, either by design or not, advance climate goals. This literature provides a good
39 starting point for assessing these partnerships as they become operational. These can help assess
40 whether such partnerships are worth the effort in terms of their performance and effectiveness (Liu et
41 al. 2017b), their economic and social value added (Quélin et al. 2017), their efficiency (Estache and
42 Saussier 2014) and the possible risks associated with them (Darrin, Grimsey and Mervyn 2002).

43 What is less common, but gradually growing, is an important and more relevant literature on criteria to
44 assess sustainability and impact on climate and development goals. Michaelowa and Michaelowa assess
45 109 trans-national partnerships and alliances based on four design criteria: existence of mitigation
46 targets; incentives for mitigation; definition of a baseline; and existence of a monitoring, reporting, and
47 verification procedure (Michaelowa and Michaelowa 2017). About half of the initiatives do not meet
48 any of these criteria, and not even 15% satisfy three or more. A recent study using a systematic review

1 of business and public administration literature on PPPs concludes that research in the past rarely
2 incorporates sustainability concepts. The authors propose a research agenda and a series of success
3 factors that, if appropriately managed can contribute to sustainable development, and in so doing
4 contribute to a more solid scientific evaluation of PPPs (Pinz et al. 2018). There is evidence that with
5 the adoption of the Sustainable Development Goals (SDGs), many of which are directly linked to
6 climate goals, PPPs will become even more prominent as they will be called upon to provide resources,
7 knowledge, expertise, and implementation support in a very ambitious agenda. PPT in the developing
8 world needs to take into account different cultural and social decision making processes, language
9 differences, and unfamiliar bureaucracy (Gardiner et al. 2016). Having more evidence on what norms
10 and standards in relation to sustainability are used and their governance is essential (Axel 2019). The
11 issue of double counting should be revised. GHGs are accounted both at the national and sub-national
12 level or company level (Schneider et al. 2014). Some recent studies aim to provide systems to assess
13 the impact of PPPs beyond the much-used notion of value for money. One of these recent studies
14 proposes a conceptual model that addresses six dimensions relevant to economic, social and
15 environmental progress. These include resilience and environment, access of services to the population,
16 scalability and replicability, economic impact, inclusiveness, and finally, degree of engagement of
17 stakeholders (Berrone et al. 2019). These systems will most likely continue to evolve.

18 19 **14.5.5 International co-operation at the sub-national and city levels**

20 Local and regional governments have an important role to play in global climate action, something
21 recognised by the Paris Agreement, and also assessed in Chapter 13 of this report, sections 13.3.2 and
22 13.3.4. There are several ways they can be useful. First, subnational governments can contribute insights
23 and experience that provide valuable lessons to national governments, as well as offering needed
24 implementation capacity (GIZ 2017; Leffel 2018). A great deal of policymaking has occurred at the
25 level of city governments in particular. Cities have been responsible for more than 70% of global
26 greenhouse gas (GHG) emissions and generate over 80% of global income (World Bank 2010), and
27 many of them have started to take their own initiative in enacting and developing mitigation policies
28 (CDP 2015). Most of these activities aim at the reduction of GHG emissions in the sectors of energy,
29 transportation, urban land use and waste (Bulkeley 2010; Xuemei 2007), and are motivated by concerns
30 not only over climate, but also a consideration of local co-benefits (Rashidi et al. 2017, 2019). Second,
31 sub-national governments can fill the void in policy leadership in cases where national governments are
32 ineffectual, even to the point of claiming leadership and authority with respect to foreign affairs (Leffel
33 2018). International cooperation plays a role in such action. Several international networks, such as
34 C40, ICLEI, Mayors for Climate Protection, and the Covenant of Mayors have played an important role
35 in defining and developing climate-policy initiatives at the city level (Fünfgeld 2015). While the
36 networks differ from each other, they generally are voluntary and non-hierarchical, intended to support
37 the horizontal diffusion of innovative climate policies through information sharing platforms linked to
38 specific goals that member cities make (Kern and Bulkeley 2009). The literature has addressed the
39 questions of why cities join the networks (Betsill and Bulkeley 2004; Pitt 2010), what recognition
40 benefits cities can expect (Buis 2009; Kern and Bulkeley 2009), and how memberships can provide
41 visibility to leverage international funding (Betsill and Bulkeley 2004; Heinrichs et al., 2013).
42 Membership in the networks has been found to be a significant predictor of cities' adoption of mitigation
43 policies, even when controlling for national-level policies that may be in place (Rashidi and Patt 2018).
44 Kona et al. (2018) find that cities belonging to the Covenant of Mayors are engaging in emissions
45 reductions at a rate consistent with achieving a 2°C global temperature target. Kona et al. (2021)
46 document this trend continuing.

47 With respect to their role in formal international cooperation, however, it is unclear what authority, as
48 a non-state actor, they actually have. Cities, for example, are members of transnational initiatives aimed

1 at non-state actors, such as Global Climate Action, originally the Non-state Actor Zone for Climate
2 Action, under the UNFCCC. While there is reason to believe that such membership can add value to
3 mitigation efforts, one study suggests that the environmental effects have yet to be reliably quantified
4 (Hsu et al. 2019a). By contrast, Kuramochi et al. (2020) provide evidence that non-state actors are
5 leading to significant emission reductions beyond what countries would otherwise be achieving. In
6 terms institutional strength, Michaelowa and Michaelowa (2017) suggest that few such networks fulfil
7 governance criteria, and hence challenge their effectiveness. Several researchers suggest that their role
8 is important in informal ways, given issues about the legitimacy of non-state actors (Nasiritousi et al.
9 2016; Chan et al. 2016). Bäckstrand et al. (2017) advance the concept of ‘hybrid multilateralism’ as a
10 heuristic to capture this intensified interplay between state and non-state actors in the new landscape of
11 international climate cooperation. The effectiveness of such non-state government actors should be
12 measured not only by their contribution to mitigation, but also by their success to enhance the
13 accountability, transparency and deliberative quality of the UNFCCC and the Paris Agreement (Busby
14 2016; Hale et al. 2016; Chan et al. 2015). In the post-Paris era, effectiveness also revolves around how
15 to align non-state and intergovernmental action in a comprehensive framework that can help achieve
16 low carbon futures (Chan et al. 2016). Stua (2017b) suggests that networks involving non-state actors
17 can play an important role in enhancing transparency. Such effectiveness has to be complemented also
18 by *normative questions*, applying a set of democratic values: participation, deliberation, accountability,
19 and transparency (Bäckstrand and Kuyper 2017). Such concepts of polycentric governance offer new
20 opportunities for climate action, but it has been argued that it is too early to judge its importance
21 and effects (Jordan et al. 2015).

24 14.6 Synthesis

25 14.6.1 Changing nature of international cooperation

26 The main development since AR5 in terms of international climate cooperation has been the shift from
27 the Kyoto Protocol to the Paris Agreement as the primary multilateral driver of climate mitigation policy
28 worldwide (Section 14.3). Most *ex-post* assessments of the Kyoto Protocol suggest that it did lead to
29 emissions reductions in countries with binding targets, in addition to changing investment patterns in
30 low-carbon technologies. As noted earlier, the Paris Agreement is tailored to the evolving understanding
31 of the climate mitigation challenge as well as shifting political imperatives and constraints. Whether the
32 Paris Agreement will in fact be effective in supporting global action sufficient to achieve its objectives
33 is contested, with competing arguments in the scientific literature supporting different views. To some
34 extent these views align with the different analytic frameworks (Section 14.2.1): the Paris Agreement
35 does not address the free-riding issue seen as important within the global commons framing, but may
36 provide the necessary incentives and support mechanisms viewed as important under the political and
37 transitions framings, respectively. The strongest critique of the Paris Agreement is that current NDCs
38 themselves fail by a wide margin to add up to the level of aggregate emissions reductions necessary to
39 achieve the objectives of holding global average warming well below 2°C, much less 1.5°C (see Section
40 14.3.3 and Figure 14.2), and that there is no legally binding obligation to achieve the NDCs. Arguments
41 in support of Paris are that it puts in place the processes, and generates normative expectations, that
42 nudge NDCs to become progressively more ambitious over time, including in developing countries.
43 The growing number of countries with mid-century net zero GHG or CO₂ targets, consistent with
44 Article 4 of Paris, lends support to this proposition, although there is as yet no empirical literature
45 drawing an unambiguous connection. The collective quantified goal from a floor of USD100 billion a
46 year in transfers to developing countries, the Green Climate Fund and other provisions on finance in
47 the Paris Agreement have also been recognised as key to cooperation (Sections 14.3.2.8 and 14.4.1).

1 But then these arguments are met with counter arguments, that even with Paris processes in place, given
2 the logic of iterative, rising levels of ambition over time, this is unlikely to happen within the narrow
3 window of opportunity that exists to avert dangerous levels of global warming (Section 14.3.3). The
4 degree to which countries are willing to increase the ambition and secure the achievement of their NDCs
5 over time will be an important indicator of the success of the Paris Agreement; evidence of this was
6 expected by the end of 2020, but the COVID-19 pandemic has delayed the process of updating NDCs.

7 An increasing role is also played by other cooperative agreements, in particular (potentially) under
8 Article 6 (Sections 14.3.2.10 and 14.4.4), trans-national partnerships, and the institutions that support
9 them. This fits both a transitions narrative that cooperation at the sub-global and sectoral levels is
10 necessary to enable specific system transformations, and a recent emphasis in the public goods literature
11 on club goods and a gradual approach to cooperation, also referred to as building blocks or incremental
12 approach (Sections 14.2 and 14.5.1.4). There has been little analysis of whether these other agreements
13 are of sufficient scale and scope to ensure that transformations happen quickly enough. This chapter,
14 appraising them together, concludes that they are not. First, many agreements, such as those related to
15 trade, may stand in the way of bottom-up mitigation efforts (Section 14.5.1.3). Second, many sectoral
16 agreements aimed at decarbonisation – such as within the air travel sector – have not yet adopted targets
17 comparable in scale, scope or legal character to those adopted under the Paris Agreement (Section
18 14.5.2.3). Third, there are many sectors for which there are no agreements in place. At the same time,
19 there are some important bright spots, many in the area of trans-national partnerships. A growing
20 number of cities have committed themselves to adopting urban policies that will place them on a path
21 to rapid decarbonisation, while learning from each other how to implement successful policies to realise
22 climate goals (Section 14.5.5). An increasing number of large corporations have committed to
23 decarbonising their industrial processes and supply chains (Section 14.5.4). And, an ever-increasing
24 number of non-state actors are adopting goals and initiating mitigation actions (Section 14.5.3). These
25 goals and actions, some argue, could bridge the mitigation gap created by inadequate NDCs, although
26 the empirical literature to date challenges this, suggesting that there is less transparency and limited
27 accountability for such actions, and mitigation targets and incentives are also not clear (Sections 14.3.3
28 and 14.5).

30 **14.6.2 Overall assessment of international cooperation**

31 This section provides an overall assessment of international cooperation, taking into account the
32 combined effects of cooperation within the UNFCCC process, other global agreements, as well as
33 regional, sectoral, and transnational processes. Recent literature consistent with the transitions framing
34 highlights that cooperation can be particularly effective when it addresses issues on a sector-by-sector
35 basis (Geels et al. 2019). Table 14.4 below summarises the effects of international cooperation on
36 mitigation efforts in each of the sectoral areas covered in Chapter 5 – 12 of this Assessment Report. As
37 it indicates, there are some strong areas of sectoral-specific cooperation, but also some important
38 weaknesses. Formal agreements and programs, both multilateral and bilateral, are advancing mitigation
39 efforts in energy, AFOLU, and transportation, while transnational networks and partnerships are
40 addressing issues in urban systems, industry, and buildings. Although many of the concerns relevant
41 for buildings may be embedded in the energy sector with respect to their operation, and the industrial
42 sector with respect to their materials, reinforcing the networks with more formal agreements could be
43 vital to putting these sectors on a pathway to net zero GHG or CO₂ emissions. Several of the sectors
44 have very little formal cooperation at the international level, and a common theme across many of them
45 is a need for increased financial flows to achieve particular objectives.

1

Table 14.4 Effects of international cooperation on sectoral mitigation efforts

Sector	Key strengths	Key gaps and weaknesses
Demand, services, social aspects	Adoption of SDGs addressing social inequities and sustainable development in the context of mitigation.	Little international attention to demand-side mitigation issues.
Energy	Greater incorporation of climate goals into sectoral agreements and institutions; formation of new specialised agencies (e.g. IRENA, SE4All) devoted to climate-compatible energy.	Need for enhanced financial support to place low-carbon energy sources on an equal footing with carbon emitting energy in developing countries; investor-state dispute settlement mechanisms designed to protect the interests of companies engaged in high-carbon energy supply from national policies; ensuring just transition; and, addressing stranded assets.
AFOLU	Bilateral support for REDD+ activities; transnational partnerships disincentivising use of products from degraded lands.	Need for increased global finance for forest restoration projects and REDD+ activities; failure of national governments to meet internationally agreed upon targets with respect to deforestation and restoration; no cooperative mechanisms in place to address agricultural emissions
Urban systems	Transnational partnerships enhancing the capacity of municipal governments to design and implement effective policies.	Need for increased financial support for climate compatible urban infrastructure development.
Buildings	Transnational initiative aimed at developing regional roadmaps.	Need for formal international cooperation to enhance mitigation activities in buildings.
Transport	Sectoral agreements in aviation and shipping begin to address climate concerns.	Need to raise the level of ambition in sectoral agreements consistent with the Paris Agreement and complete decarbonisation, especially as emissions from international aviation and shipping continue to grow, unaccounted for in NDCs.
Industry	Transnational partnerships and networks encouraging the adoption of zero emission supply chain targets.	No formal multilateral or bilateral cooperation to address issues of decarbonisation in industry.
Cross-sectoral, including CDR and SRM	International agreements addressing risks of ocean-based CDR	Lack of cooperative mechanisms addressing risks and benefits of SRM; lack of cooperative mechanisms addressing financial and governance aspects of land- and technology-based CDR.

2

3 Table 14.5 provides examples of mechanisms addressing each of the assessment criteria identified in
4 Section 14.2.3. The effects of different forms of international cooperation are separated out, including
5 not only UNFCCC and other multilateral processes, but also sub-global and sectoral agreements.
6 Several points stand out. First, the Paris Agreement has the potential to significantly advance the UN

1 climate regime's transformative potential. Second, the international market mechanisms under Article
 2 6 – should an agreement on implementation deals be reached – allow a shift from projects and programs
 3 to policy-based and sectoral generation of emissions credits. Moreover, the sectoral agreement CORSIA
 4 also makes use of such credits. Third, there is a lack of attention to both distributive outcomes and
 5 institutional support within sectoral agreements, representing a serious gap in efforts to harmonise
 6 mitigation with equity and sustainable development. Fourth, there are transnational partnerships and
 7 initiatives, representing the actions of non-state actors, addressing each of the assessment criteria, with
 8 the exception of economic effectiveness.

9
 10 **Table 14.5 Illustrative examples of multi-level governance addressing criteria of effectiveness**

	Environmental effectiveness	Transformative potential	Distributive Outcomes	Economic effectiveness	Institutional strength
UNFCCC	Stabilisation goal, and quasi-targets for industrialised countries	Financial mechanism; technology mechanism, provisions for capacity building	Financial mechanism, transfers from developed to developing; leadership role for industrialised countries listed in Annex 1		Reporting requirements; capacity building for national climate change offices.
Kyoto Protocol	Binding national targets for industrialised countries		Adaptation Fund; targets restricted to industrialised countries	Market-based mechanisms	Emissions accounting and reporting requirements, institutional capacity building
Paris Agreement	NDCs and the global stocktake	Mechanisms for capacity building and technology development and transfer	Furthering financial commitments under the UNFCCC, including enhanced transparency on finance	Voluntary cooperation	Mechanism for enhanced transparency
Other multilateral agreements (Montreal protocol, and SDG 7, etc)	Phase out of Ozone depleting substances (ODS) with high global warming potential - significant effects on GHG mitigation	Ozone Fund, technology transfer; development and sharing of knowledge and expertise	SDGs embedding mitigation in sustainable development		Processes for adjustment and amendment, reporting requirements

Multilateral and regional economic agreements and institutions	Harmonised lending practices of MDBs; mainstreaming climate change into IMF practices; liberalisation of trade in climate-friendly goods and services; negative effect from regulatory chill		Concessional financing agreements	Potentially negative results from dispute settlement processes
Sectoral agreements and institutions	Climate mitigation targets and actions in AFOLU, energy, and transport	Institutions devoted to developing and deploying zero-carbon energy technologies (e.g. IRENA).		Use of carbon offsets to reduce growth in emissions from aviation
Transnational networks and partnerships	Youth climate movement raising mitigation and fossil fuel divestment on political agendas and in financial sector	Non-state actor commitments to renewable energy-based supply chains	Climate justice legal initiatives	City networks providing information exchange and technical support

3 14.7 Knowledge Gaps

4 Any assessment of the effectiveness of international cooperation is limited by the methodological
5 challenge of observing sufficient variance in cooperation in order to support inference on effects. There
6 is little in the way of cross-sectional variance, given that most of the governance mechanisms assessed
7 here are global in their geographical coverage. One exception is with respect to the effects of the Kyoto
8 Protocol, which we have reported. Time series analysis is also challenging, given that other
9 determinants of climate mitigation, including technology costs and the effects of national and sub-
10 national level policies, are rapidly evolving. Thus, this chapter primarily reviews scholarship that
11 compares observations with theory-based counter-factual scenarios.

12 Many of the international agreements and institutions discussed in this chapter, in particular the Paris
13 Agreement, are new. The logic and architecture of the Paris Agreement, in particular, breaks new
14 ground, and there is limited evaluation of prior experience in the form of analogous treaties to draw on.
15 Such instruments have evolved in response to geo-political and other drivers, that are changing rapidly,
16 and will continue to shape the nature of international cooperation under it and triggered by it. The Paris
17 Agreement is also, in common with other multilateral agreements, a ‘living instrument’ evolving

1 through interpretative and operationalising rules, and forms of implementation, that parties continue to
2 negotiate at conferences year on year. It is a constant ‘work in progress’ and thus challenging to assess
3 at any given point in time. The Paris Agreement also engages a larger set of variables – given its
4 privileging of national autonomy and politics, integration with the sustainable development agenda, and
5 its engagement with actions and actors at multiple levels – than earlier international agreements, which
6 further complicates the task of tracing causality between observed effects and international cooperation
7 through the Paris Agreement.

8 Understanding of the effectiveness of international agreements and institutions is driven entirely by
9 theory driven prediction of how the world will evolve, both with these agreements in place and without
10 them. The former predictions in particular are problematic, because governance regimes are complex
11 adaptive systems, making it impossible to predict how they will evolve over time, and hence what their
12 effects will be. Time will cure this in part, as it will generate observations of the world with the new
13 regime in place, which we can compare to the counterfactual situation of the new regime’s being absent,
14 which may be a simpler situation to model. But even here our modelling capacity is limited: it may
15 simply never be possible to know with a high degree of confidence whether international cooperation,
16 such as that embodied in the Paris Agreement, is having a significant effect, no matter how much data
17 are accumulated.

18 Given the importance of theory for guiding assessments of the past and likely future impacts of policies,
19 it is important to note that among the alternative theoretical frameworks for analysis, some have been
20 much more extensively developed in the literature than others. This chapter has noted in particular the
21 partial dichotomy between a global-commons framing of climate change and a transitions framing,
22 which include different indicators to be used to evaluate the effectiveness of policies. The latter framing
23 is particularly under-developed. Greater development of theories resting in social science disciplines
24 such as economic geography, sociology, and psychology could potentially provide a more complete
25 picture of the nature and effectiveness of international cooperation.

28 **Frequently Asked Questions**

29 **FAQ 14.1: Is international cooperation working?**

30 Yes, to an extent. Countries’ emissions were in line with their internationally agreed targets: the
31 collective Greenhouse Gas (GHG) mitigation target for Annex I countries in the UNFCCC to return to
32 their 1990 emissions by 2000, and their individual targets in the Kyoto Protocol for 2008-12. Numerous
33 studies suggest that participation in the Kyoto Protocol led to substantial reductions in national GHG
34 emissions, as well increased levels of innovation and investment in low-carbon technologies. In this
35 latter respect, the Kyoto Protocol set in motion some of the transformational changes that will be
36 required to meet the temperature goal of the Paris Agreement. It is too soon to tell whether the processes
37 and commitments embodied in the Paris Agreement will be effective in achieving its stated goals with
38 respect to limiting temperature rise, adaptation, and financial flows. There is, however, evidence that
39 its entry into force has been a contributing factor to many countries’ adopting mid-century targets of
40 net-zero GHG or CO₂ emissions.

41 **FAQ 14.2: What is the future role of international cooperation in the context of the Paris** 42 **Agreement?**

43 Continued international cooperation remains critically important both to stimulate countries’ enhanced
44 levels of mitigation ambition, and through various means of support to increase the likelihood that they
45 achieve these objectives. The latter is particularly the case in developing countries, where mitigation

1 efforts often rely on bilateral and multilateral cooperation on low-carbon finance, technology support,
2 capacity building, and enhanced South-South cooperation. The Paris Agreement is structured around
3 nationally determined contributions (NDCs) that are subject to an international oversight system, and
4 bolstered through international support. The international oversight system is designed to generate
5 transparency and accountability for individual emission reduction contributions, and regular moments
6 for stock-taking of these efforts towards global goals. Such enhanced transparency may instil
7 confidence and trust, and foster solidarity among nations, with theory-based arguments that this will
8 lead to greater levels of ambition. Together with other cooperative agreements at the sub-global and
9 sectoral levels, as well as a growing number of transnational networks and initiatives, the
10 implementation of all of these mechanisms are likely to play an important role in making political,
11 economic, and social conditions more favourable to ambitious mitigation efforts in the context of
12 sustainable development and efforts to eradicate poverty.

13 **FAQ 14.3: Are there any important gaps in international cooperation, which will need to be filled**
14 **in order for countries to achieve the objectives of the Paris Agreement, such as holding**
15 **temperature increase to ‘well below 2°C’ and pursuing efforts towards ‘1.5°C’ above pre-**
16 **industrial levels?**

17 While international cooperation is contributing to global mitigation efforts, its effects are far from
18 uniform. Cooperation has contributed to setting a global direction of travel, and to falling greenhouse
19 gas emissions in many countries and avoided emissions in others. It remains to be seen whether it can
20 achieve the kind of transformational changes needed to achieve the Paris Agreement’s long-term global
21 goals. There appears to be a large potential role for international cooperation to better address sector-
22 specific technical and infrastructure challenges that are associated with such transformational changes.
23 Finalising the rules to pursue voluntary cooperation, such as through international carbon market
24 mechanisms and public climate finance in the implementation of NDCs, without compromising
25 environmental integrity, may play an important role in accelerating mitigation efforts in developing
26 countries. Finally, there is room for international cooperation to more explicitly address transboundary
27 issues associated with Carbon Dioxide Removal (CDR) and Solar Radiation Management (SRM).

34		

1 **Executive summary**

2 **Finance to reduce net greenhouse gas (GHG) emissions and enhance resilience to climate impacts**
3 **represents a critical enabling factor for the low carbon transition. Fundamental inequities in**
4 **access to finance as well as its terms and conditions, and countries exposure to physical impacts**
5 **of climate change overall result in a worsening outlook for a global just transition (*high***
6 ***confidence*).** Decarbonising the economy requires global action to address fundamental economic
7 inequities and overcome the climate investment trap that exists for many developing countries. For
8 these countries the costs and risks of financing often represent a significant challenge for stakeholders
9 at all levels. This challenge is exacerbated by these countries' general economic vulnerability and
10 indebtedness. The rising public fiscal costs of mitigation, and of adapting to climate shocks, is affecting
11 many countries and worsening public indebtedness and country credit ratings at a time when there were
12 already significant stresses on public finances. The COVID-19 pandemic has made these stresses worse
13 and tightened public finances still further. Other major challenges for commercial climate finance
14 include: the mismatch between capital and investment needs, home bias¹ considerations, differences in
15 risk perceptions for regions, as well as limited institutional capacity to ensure safeguards represent.
16 {15.2, 15.6.3}

17 **Investors, central banks, and financial regulators are driving increased awareness of climate risk.**
18 **This increased awareness can support climate policy development and implementation (*high***
19 ***confidence*).** Climate-related financial risks arise from physical impacts of climate change (already
20 relevant in the short term), and from a disorderly transition to a low carbon economy. Awareness of
21 these risks is increasing leading also to concerns about financial stability. Financial regulators and
22 institutions have responded with multiple regulatory and voluntary initiatives by to assess and address
23 these risks. Yet despite these initiatives, climate-related financial risks remain greatly underestimated
24 by financial institutions and markets limiting the capital reallocation needed for the low-carbon
25 transition. Moreover, risks relating to national and international inequity – which act as a barrier to the
26 transformation – are not yet reflected in decisions by the financial community. Stronger steering by
27 regulators and policy makers has the potential to close this gap. Despite the increasing attention of
28 investors to climate change, there is limited evidence that this attention has directly impacted emission
29 reductions. This leaves high uncertainty, both near-term (2021-30) and longer-term (2021-50), on the
30 feasibility of an alignment of financial flows with the Paris Agreement (*high confidence*). {15.2, 15.6}

31 **Progress on the alignment of financial flows with low GHG emissions pathways remains slow.**
32 **There is a climate financing gap which reflects a persistent misallocation of global capital (*high***
33 ***confidence*).** Persistently high levels of both public and private fossil-fuel related financing continue to
34 be of major concern despite promising recent commitments. This reflects policy misalignment, the
35 current perceived risk-return profile of fossil fuel-related investments, and political economy constraints
36 (*high confidence*). {15.3}

37 Estimates of climate finance flows – which refers to local, national, or transnational financing from
38 public, private, multilateral, bilateral and alternative sources, to support mitigation and adaptation
39 actions addressing climate change – exhibit highly divergent patterns across regions and sectors and a
40 slowing growth. {15.3}

41 When the perceived risks are too high the misallocation of abundant savings persists. Investors refrain
42 from investing in infrastructure and industry in search of safer financial assets, even earning low or
43 negative real returns. {15.2, 15.3}

FOOTNOTE ¹ Most of climate finance stays within national borders, especially private climate flows (over 90%).
Reasons are national policy support, differences in regulatory standards, exchange rate, political and governance
risks, to information market failures.

1 Global climate finance is heavily focused on mitigation (more than 90% on average between 2017-
2 2020). This is despite the significant economic effects of climate change's expected physical impacts,
3 and the increasing awareness of these effects on financial stability. To meet the needs for rapid
4 deployment of mitigation options, global mitigation investments are expected to need to increase by the
5 factor of 3 to 6 (*high confidence*). The gaps represent a major challenge for developing countries,
6 especially Least Developed Countries (LDCs), where flows have to increase by factor 4 to 8, for specific
7 sectors like AFOLU, and for specific groups with limited access to-, and high costs of-, climate finance
8 (*high confidence*). {15.4, 15.5}

9 The actual size of sectoral and regional climate financing gaps is only one component driving the
10 magnitude of the challenge, with financial and economic viability, access to capital markets, appropriate
11 regulatory frameworks and institutional capacity to attract and facilitate investments and ensure
12 safeguards being decisive to scale-up financing. Financing needs for the creation and strengthening of
13 regulatory environment and institutional capacity, upstream financing needs as well as R&D and
14 venture capital for development of new technologies and business models are often overlooked despite
15 their critical role to facilitate the deployment of scaled-up climate finance (*high confidence*). {15.4.1,
16 15.5.2}

17 **The relatively slow implementation of commitments by countries and stakeholders in the financial**
18 **system to scale up climate finance reflects neither the urgent need for ambitious climate action,**
19 **nor the economic rationale for ambitious climate action. (*high confidence*).** Delayed climate
20 investments and financing – and limited alignment of investment activity with the Paris Agreement –
21 will result in significant carbon lock-ins, stranded assets, and other additional costs. This will
22 particularly impact urban infrastructure and the energy and transport sectors (*high confidence*). A
23 common understanding of debt sustainability and debt transparency, including negative implications of
24 deferred climate investments on future GDP, and how stranded assets and resources may be
25 compensated, has not yet been developed (*medium confidence*). {15.6}

26 The greater the urgency of action to remain on a 1.5°C pathway the greater need for parallel investment
27 decisions in upstream and downstream parts of the value chain. Greater urgency also reduces the lead
28 times to build trust in regulatory frameworks. Consequently, many investment decisions will need to be
29 made based on the long-term global goals. This highlights the importance of trust in political leadership
30 which, in turn, affects risk perception and ultimately financing costs (*high confidence*). {15.6.1, 15.6.2}

31 There is a mismatch between capital availability in the developed world and the future emissions
32 expected in developing countries. This emphasizes the need to recognize the explicit and positive social
33 value of global cross-border mitigation financing. A significant push for international climate finance
34 access for vulnerable and poor countries is particularly important given these countries' high costs of
35 financing, debt stress and the impacts of ongoing climate change (*high confidence*). {15.2, 15.3.2.3,
36 15.5.2, 15.6.1, 15.6.7}

37 **Ambitious global climate policy coordination and stepped-up (public) climate financing over the**
38 **next decade (2021–2030) can help address macroeconomic uncertainty and alleviate developing**
39 **countries' debt burden post-COVID-19. It can also help redirect capital markets and overcome**
40 **challenges relating to the need for parallel investments in mitigation and the up-front risks that**
41 **deter economically sound low carbon projects. (*high confidence*)** Providing strong climate policy
42 signals helps guide investment decisions. Credible signalling by governments and the international
43 community can reduce uncertainty for financial decision-makers and help reduce transition risk. In
44 addition to indirect and direct subsidies, the public sector's role in addressing market failures, barriers,
45 provision of information, and risk sharing (equity, various forms of public guarantees) can encourage
46 the efficient mobilisation of private sector finance (*high confidence*). {15.2, 15.6.1, 15.6.2}

47 The mutual benefits of coordinated support for climate mitigation and adaptation in the next decade for
48 both developed and developing regions could potentially be very high in the post-Covid era. Climate
49 compatible stimulus packages could significantly reduce the macro-financial uncertainty generated by

1 the pandemic and increase the sustainability of the world economic recovery. {15.2, 15.3.2.3, 15.5.2,
2 15.6.1, 15.6.7}

3 Political leadership and intervention remains central to addressing uncertainty as a fundamental barrier
4 for a redirection of financial flows. Existing policy misalignments – for example in fossil fuel subsidies
5 – undermine the credibility of public commitments, reduce perceived transition risks and limit financial
6 sector action (*high confidence*). {15.2, 15.3.3, 15.6.1, 15.6.2, 15.6.3}

7 **Innovative financing approaches could help reduce the systemic underpricing of climate risk in**
8 **markets and foster demand for Paris-aligned investment opportunities. Approaches include de-**
9 **risking investments, robust ‘green’ labelling and disclosure schemes, in addition to a regulatory**
10 **focus on transparency and reforming international monetary system financial sector regulations**
11 **(*medium confidence*)**. Green bond markets and markets for sustainable finance products have grown
12 significantly since AR5 and the landscape continues to evolve. Underpinning this evolution is investors’
13 preference for scalable and identifiable low-carbon investment opportunities. These relatively new
14 labelled financial products will help by allowing a smooth integration into existing asset allocation
15 models. (*high confidence*) Green bond markets and markets for sustainable finance products have also
16 increased significantly since AR5, but challenges nevertheless remain, in particular there are concerns
17 about ‘greenwashing’ and the limited application of these markets to developing countries. New
18 business models (e.g. pay-as-you-go) can facilitate the aggregation of small-scale financing needs and
19 provide scalable investment opportunities with more attractive risk-return profiles. Support and
20 guidance for enhancing transparency can promote capital markets’ climate financing by providing
21 quality information to price climate risks and opportunities. Examples include sustainable development
22 goals (SDG) and environmental, social and governance (ESG) disclosure, scenario analysis and climate
23 risk assessments, including the Task Force on Climate-Related Financial Disclosures (TCFD). The
24 outcome of these market-correcting approaches on capital flows cannot be taken for granted, however,
25 without appropriate fiscal, monetary and financial policies. Mitigation policies will be required to
26 enhance the risk-weighted return of low emission and climate resilient options, and - supported by
27 progress in transparent and scientifically based projects’ assessment methods - to accelerate the
28 emergence and support for financial products based on real projects, such as green bonds, and phase
29 out fossil fuel subsidies. Greater public-private cooperation can also encourage the private sector to
30 increase and broaden investments, within a context of safeguards and standards, and this can be
31 integrated into national climate change policies and plans. {15.1, 15.2.4, 15.3.1, 15.3.2, 15.3.3, 15.5.2,
32 15.6.1, 15.6.2, 15.6.6, 15.6.7, 15.6.8}.

33 **The following policy options can have important long-term catalytic benefits (*high confidence*).**
34 (i) Stepped-up both the quantum and composition of financial, technical support and partnership in low-
35 income and vulnerable countries alongside low-carbon energy access in low-income countries, such as
36 Sub-Saharan Africa, which currently receives less than 5% of global climate financing flows; (ii)
37 continued strong role of international and national financial institutions, including multilateral,
38 especially location-based regional, and national development banks; (iii) de-risking cross-border
39 investments in low-carbon infrastructure, development of local green bond markets, and the alignment
40 of climate and non-climate policies, including direct and in-direct supports on fossil fuels, consistent
41 with the climate goals; (iv) lowering financing costs including transaction costs and addressing risks
42 through funds and risk-sharing mechanisms for under-served groups; (v) accelerated finance for nature-
43 based solutions, including mitigation in the forest sector (REDD+), and climate-responsive social
44 protection; (vi) improved financing instruments for loss and damage events, including risk-pooling-
45 transfer-sharing for climate risk insurance; (vii) phasing-in carbon pricing and phasing out fossil fuel
46 subsidies in a way that addresses equity and access; and (viii) gender-responsive and women
47 empowered programs {15.2.3, 15.2.4, 15.3.1, 15.3.2.2, 15.3.3, 15.4.1, 15.4.2, 15.4.3, 15.5.2, 15.6,
48 15.6.2, 15.6.4, 15.6.5, 15.6.6, 15.6.7, 15.6.8.2}.

49

1 15.1 Introduction

2 15.1.1 Climate finance - key concepts and elements of scope

3 Finance for climate action (or climate finance), environmental finance (which also covers other
4 environmental priorities such as water, air pollution and biodiversity), and sustainable finance (which
5 encompasses issues relating to socio-economic impacts, poverty alleviation and empowerment) are
6 interrelated rather than mutually exclusive concepts (UNEP Inquiry 2016a; ICMA 2020a). Their
7 combination is needed to align mitigation investments with multiple SDGs, at a minimum, minimize
8 the conflicts between climate targets and SDGs not being targeted. From a climate policy perspective,
9 climate finance refers to finance “whose expected effect is to reduce net GHG emissions and/or enhance
10 resilience to the impacts of climate variability and projected climate change” (UNFCCC 2018a).
11 However, as pinpointed in the AR5, significant room for interpretation and context-specific
12 considerations remain. Further, such definition needs to be put in perspective with the expectations of
13 investors and financiers (see Box 15.2).

14 Specifying the scope of climate finance requires defining two terms: what qualifies as “finance” and as
15 “climate” respectively. In terms of what type of finance to consider, options include considering
16 investments or total costs (see Box 15.1), stocks or flows, gross or net (the latter taking into account
17 reflows and/or depreciation), and domestic or cross-border, public or private (see Box 15.2). In terms
18 of what may be considered as “climate”, a key difference relates to measuring climate-specific finance
19 (only accounts for the portion finance resulting in climate benefits) or climate-related finance (captures
20 total project costs and aims to measure the mainstreaming of climate considerations). One should even
21 consider the investments decided for reasons unrelated with climate objectives but contribute to these
22 objectives (hydroelectricity, rail transportation).

23 **‘START BOX 15.1 HERE’**

24 **Box 15.1 Core Terms**

25 This box defines some core terms used in this chapter as well as in other chapters addressing finance
26 issues: cost, investment, financing, public and private. The chapter makes broad use of the *finance* to
27 refer to all types of transactions involving monetary amounts. It avoids the use of the terms *funds* and
28 *funding* to the extent possible, which should otherwise be understood as synonyms for *money* and *money*
29 *provided*.

30 **Cost, investment and financing: different but intertwined concepts.** Cost encompass capital
31 expenditures (CAPEX or upfront investment value leveraged over the lifetime of a project) operating
32 and maintenance expenditures (OPEX), as well as financing costs. Note that some projects e.g. related
33 to technical assistance may only involve OPEX (e.g. staff costs) but no CAPEX, or may not incur direct
34 financing costs (e.g. if fully financed via own funds and grants).

35 *Investment*, in an economic sense, is the purchase of (or CAPEX for) a physical asset (notably
36 infrastructure or equipment) or intangible asset (e.g. patents, IT solutions) not consumed immediately
37 but used over time. For financial investors, physical and intangible assets take the form of financial
38 assets such as bonds or stocks which are expecting to provide income or be sold at a higher price later.
39 In practice, investment decisions are motivated by a calculation of risk-weighted expected returns that
40 takes into account all expected costs, as well as the different types of risks, discussed in Section 15.6.1,
41 that may impact the returns of the investment and even turn them into losses.

42 *Incremental cost (or investment)* accounts for the difference between the cost (or investment value) for
43 a climate projects compared to the cost (or investment value) of a counterfactual reference project (or
44 investment). In cases where climate projects and investments are more cost effective than the
45 counterfactual, the incremental cost will be negative.

1 Financing refers to the process of securing the money needed to cover an investment or project cost.
2 Financing can rely on debt (e.g. through bond issuance or loan subscription), equity issuances (listed or
3 unlisted shares), own funds (typically savings or auto-financing through retained earnings), as well as
4 on grants and subsidies

5 **Public and private: statistical standard and grey zones.** International statistics classify economic
6 actors as pertaining to the public or private sectors. Households always qualify as private and
7 governmental bodies and agencies as public. Criteria are needed for other types of actors such as
8 enterprises and financial institutions. Most statistics rely on the majority ownership and control
9 principle. This is the case for the Balance of Payment, which records transactions between residents of
10 a country and the rest of the world (IMF 2009).

11 Such a strict boundary between public and private sectors may not always be suitable for mapping and
12 assessing investment and financing activities. On the one hand, some publicly owned entities may have
13 a mandate to operate on a fully- or semi-commercial basis, e.g. state-owned enterprises, commercial
14 banks, and pension funds, as well as sovereign wealth funds. On the other hand, some privately owned
15 or -controlled entities can pursue non-for profit objectives, e.g. philanthropies and charities. The present
16 chapter considers these nuances to the extent made possible by available data and information.

17 **‘END BOX 15.1 HERE**

18 In many cases, the scope of what may be considered as “climate finance” will also depend on the context
19 of implementation such as priorities and activities listed in NDCs (UNFCCC 2019a) as well as national
20 development plans more broadly targeting the achievement of SDGs. Hence, rather than opposing the
21 different options listed above, the choice of one or the other depends on the desired scope of
22 measurement, which in turn depends on the policy objective being pursued. The increasingly diverse
23 initiatives and body of grey literature address a range of different information needs. They provide
24 analyses at the levels of domestic finance flows (e.g. (UNDP 2015; Hainaut and Cochran 2018)),
25 international flows (e.g. (OECD 2016; AfDB et al. 2018)), global flows (UNFCCC 2018a; Buchner et
26 al. 2019)), the financial system (e.g. (UNEP Inquiry 2016a) or specific financial instruments such as
27 bonds (e.g. (CBI 2018)). Common frameworks, reporting transparency are, however, necessary in order
28 to identify overlaps, commonalities and differences between these different measurements in terms of
29 scope and underlying definitions. In that regard, the developments of national and international
30 taxonomies, definitions and standards can help, as further discussed in Section 15.6. and Chapter 17 in
31 WGII (TSU please confirm).

32 **‘START BOX 15.2 HERE**

33 **Box 15.2 International climate finance architecture**

34 International climate finance can flow through different bilateral, multilateral, and other channels,
35 involving a range of different types of institutions both public (official) and private (commercial) with
36 different mandates and focuses. In practice, the architecture of international public climate finance is
37 rapidly evolving, with the creation by traditional donors of new public sources and channels of over the
38 years (Watson and Schalatek 2019), as well as emergence of new providers of development co-
39 operation, both bilateral (see (Benn and Luijckx 2017)) and multilateral (e.g. Asian Infrastructure
40 Investment Bank), as well as of non-governmental actors such as philanthropies (OECD 2018a).

41 The operationalisation of the Green Climate Fund (GCF), which channels the majority of its funds via
42 accredited entities, has notably attracted particular attention since AR5. Section 14.3.2 of Chapter 14
43 provides a further assessment of progress and challenges of financial mechanisms under the UNFCCC,
44 such as the GCF, the Global Environment Facility (GEF) and the Adaptation Fund (AF).

1 The multiplication of sources and channels of international climate finance can help address growing
2 climate-related needs, and partly results from increased decentralisation as well financial innovation,
3 which in turn can increase the effectiveness of finance provided. There is, however, also evidence that
4 increased complexity implies transaction costs (Brunner and Enting 2014), in part due to bureaucracy
5 and intra-governmental factors (Peterson and Skovgaard 2019), which constitutes a barrier to low
6 carbon projects and are often not accounted for in assessments of international climate finance. On the
7 ground, activities by international providers operating in the same countries may overlap, with sub-
8 optimal coordination and hence duplication of efforts, both on the bilateral and multilateral sides
9 (Ahluwalia et al. 2016; Gallagher et al. 2018; Humphrey and Michaelowa 2019), as well as risks of
10 fragmentation of efforts (Watson and Schalatek 2020) which slows down coordination with
11 international providers, national development banks and other domestic institutions.

12 **‘END BOX 15.2 HERE’**

13 Beyond the need to scale up levels of climate finance, the Paris Agreement provides a broad policy
14 environment and momentum for a more systemic and transformational change in investment and
15 financing strategies and patterns. Article 2.1c, which calls for “making finance flows consistent with a
16 pathway towards low greenhouse gas emissions and climate-resilient development”, positions finance
17 as one of the Agreement’s three overarching goals (UNFCCC 2015). This formulation is a recognition
18 that the mitigation and resilience goals cannot be achieved without finance, both in the real economy
19 and in the financial system, being made consistent with these goals (Zamarioli et al. 2021). It has in
20 turn contributed to the development of the concept of alignment (with the Paris Agreement) used in the
21 financial sector (banks, institutional investors), businesses, and public institutions (development banks,
22 public budgets). As a result, since AR5, in addition to measuring and analysing climate finance, an
23 increasing focus has been placed on assessing the consistency or alignment, as well as respectively the
24 inconsistency or misalignment, of finance with climate policy objectives, as for instance illustrated by
25 the multilateral development banks joint framework for aligning their activities with the goals of the
26 Paris Agreements (MDBs 2018).

27 Assessing climate consistency or alignment implies looking at all investment and financing activities,
28 whether they target, contribute to, undermine or have no particular impact on climate objectives. This
29 all-encompassing scope notably includes remaining investments and financing for high-GHG emission
30 activities that may be incompatible with remaining carbon budgets, but also activities that may play a
31 transition role in climate mitigation pathways and scenarios (see Section 15.3.2.3). As a result, any
32 meaningful assessments of progress requires implies the use of different shades to assess activities based
33 on their negative, neutral (“do no harm”) or positive contributions, e.g. (CICERO 2015; Cochran and
34 Pauthier 2019; Natixis 2019). Doing so in practice requires the development of robust definitions,
35 assessment methods and metrics, an area of work and research that remained under development at the
36 time of writing. A range of financial sector coalitions, civil society organisations as well as commercial
37 services providers to the financial industry have developed frameworks, approaches and metrics, mainly
38 focusing on investment portfolios (Raynaud et al. 2020; IIGCC 2021; TCFD Portfolio Alignment Team
39 2021; U.N.-Convened Net-Zero Asset Owner Alliance 2021), and, to a lesser extent for real economy
40 investments (Micale et al. 2020; Jachnik and Dobrinevski 2021).

41 **Key findings from AR5 and other IPCC publications**

42 For the first time the IPCC in AR5 (Clarke et al. 2014) elaborated on the role of finance in a dedicated
43 chapter. In the following year, the Paris Agreement (PA) (UNFCCC 2015) recognised the
44 transformative role of finance, as a means to achieving climate outcomes, and the need to align financial
45 flows with the long-term global goals even as implementation issues were left unresolved (Bodle and
46 Noens 2018). AR5 noted the absence of a clear definition and measurement of climate finance flows, a
47 difficulty that continues (see Sections 15.2 and 15.3) (Weikmans and Roberts 2019). The approach
48 taken in AR5 was to report ranges of available information on climate finance flows from diverse

1 sources, using a broad definition of climate finance, as in the Biennial Assessments in 2014 and again
2 in 2018 (UNFCCC 2014a, 2018a) of the Standing Committee under the United Nations Framework
3 Convention on Climate Change (UNFCCC): Climate finance is taken to refer to local, national or
4 transnational financing – drawn from public, private and alternative sources of financing – that seeks to
5 support mitigation and adaptation actions that address climate change (UNFCCC 2014b). For this
6 chapter, while the focus is primarily on mitigation, adaptation, resilience and loss and damage financing
7 needs cannot be entirely separated because of structural relationships, synergies, trade-offs and policy
8 coherence requirements between these sub-categories of climate finance (Box 15.1).

9 **‘START BOX 15.3 HERE’**

10 **Box 15.3 Mitigation, adaptation and other related climate finance merit joint examination**

11 Mitigation finance deals with investments that aim to reduce global carbon emissions, while adaptation
12 finance deals with the consequences of climate change (Lindenberg and Pauw 2013). Mitigation affects
13 the scale of adaptation needs and adaptation may have strong synergies and co-benefits as well as trade-
14 offs with mitigation (Grafakos et al. 2019). If mitigation investments are inadequate to reducing global
15 warming (as in last decade) with asymmetric adverse impacts in lower latitudes and low-lying
16 geographies, the scale of adaptation investments has to rise and the benefits of stronger adaptation
17 responses may be high (Markandya and González-Eguino 2019). If adaptation investments build greater
18 resilience, they might even moderate mitigation financing costs. Similar policy coherence
19 considerations apply to disaster risk reducing financing, the scale of which depends on success with
20 both adaptation and mitigation (Mysiak et al. 2018). The same financial actors, especially governments
21 and the private sector, decide at any given time on their relative allocations of available financing for
22 mitigation, adaptation and disaster-risk from a constrained common pool of resources. The trade-offs
23 and substitutability between closely-linked alternative uses of funds, therefore, make it essential for a
24 simultaneous assessment of needs – as in parts of this chapter. Climate finance versus the financing of
25 other Sustainable Development Goals (SDGs) faces a similar issue. A key agreement was that climate
26 financing should be ‘new and additional’ and not at the cost of SDGs. Resources prioritising climate at
27 the cost of non-climate development finance increases the vulnerability of a population for any given
28 level of climate shocks, and additionality of climate financing is thus essential (Brown et al. 2010).
29 Policy coherence is also the reason why mitigation finance cannot be separated from consideration of
30 spending and subsidies on fossil fuels. Climate change may additionally cause the breaching of physical
31 and social adaptation limits, resulting in climate-related residual risks (i.e. potential impacts after all
32 feasible mitigation, adaptation, and disaster risk reduction measures, have been implemented) (Mechler
33 et al. 2020). Because these residual losses and damages from climate-related risks are related to overall
34 mitigation and adaptation efforts, the magnitude of potential impacts are related to the overall quantum
35 of mitigation, adaptation, and disaster risk reduction finance available (Frame et al. 2020). All
36 categories of climate finance thus need to be considered together in discussions around climate finance.

37 **‘END BOX 15.3 HERE’**

38 The AR5 concluded that published assessments of financial flows whose expected effect was to reduce
39 net greenhouse gas (GHG) emissions and/or to enhance resilience to climate change aggregated 343-
40 385 billion USD yr⁻¹ globally between 2010 and 2012 (*medium confidence*). Most (95% of total) went
41 towards mitigation, which nevertheless underfinanced and adaptation even more so. Measurement of
42 progress towards the commitment by developed countries to provide 100 billion USD yr⁻¹ by 2020 to
43 developing countries, for both mitigation and adaptation (Bhattacharya et al. 2020) – a narrower goal
44 than overall levels of climate finance – continued to be a challenge, given the lack of clear definition of
45 such finance, although there remain divergent perspectives (see Section 15.2.4). As against these flows,
46 annual need for global aggregate mitigation finance between 2020 and 2030 was cited briefly in the
47 AR5 to be about 635 billion USD (mean annual), both public and private, implying that the reported

1 ‘gap’ in mitigation financing of estimated flows during 2010 to 2012 was slightly under one-half of that
2 required (IPCC 2014).

3 More recent published data from the Biennial Assessments (UNFCCC 2018a) and the Special Report
4 on Global Warming of 1.5°C (IPCC 2018) have revised upwards the needs of financing between 2020
5 and 2030 to 2035 to contain global temperature rise to below 2°C and 1.5°C respectively by 2100: 1.7
6 trillion USD yr⁻¹ (mean) in the Biennial Assessment 2018 for the former, and for the latter, 2.4 trillion
7 USD yr⁻¹ (mean) for the energy sector alone (and three-times higher if transport and other sectors were
8 to be included). The resulting estimated gaps in annual mitigation financing during 2014 to 2017, using
9 reporting of climate financing from published sources was about 67% for 2015, and 76% for the energy
10 sector alone in 2017 (*medium confidence*), and greater if other sectors were to be included. While the
11 annual reported flows of climate financing showed some moderate progress (see Section 15.3), from
12 earlier 364 billion USD (mean 2010/2011) to about 600 billion USD (mean 2017/2020), with a slowing
13 in the most recent period 2014 to 2017, the gap in financing was reported to have widened considerably
14 (see Section 15.4 and 15.5). In the context of policy coherence, it is also important to note that reported
15 annual investments going into the fossil-fuel sectors, oil and gas upstream and coal mining, during the
16 same period were about the same size as global climate finance, although the absence of alternative
17 financing and access to low carbon energy is a complicating factor.

18 Adaptation financing needs, meanwhile, were rising rapidly. The Adaption Gap Report 2020 (UNEP
19 2021) reported that the current efforts are insufficient to narrow the adaptation finance gap, and
20 additional adaptation finance is necessary, particularly in developing countries. The gap is expected to
21 be aggravated by COVID-19 (*high confidence*). It reaffirmed earlier assessments that by 2030 (2050)
22 the estimated costs of adaptation ranges between 140-300 billion (280-500 billion). Against this, the
23 reported actual global public finance flows for adaptation in 2019/2020 were estimated at 46 billion
24 (Naran et al. 2021). The costs of climate disasters meanwhile continued to rise, affecting low-income
25 developing countries the most. Climate natural disasters – not all necessarily attributable to climate
26 change – caused some 300 billion USD yr⁻¹ economic losses and well-being losses of about 520 billion
27 USD yr⁻¹ (Hallegatte et al. 2017).

28

29 **15.2 Background considerations**

30 The institutions under climate finance in this chapter refer to the set of financial actors, instruments and
31 markets that are recognised to play a key role in financing decisions on climate mitigation and
32 adaptation. For a definition of climate financial stock and flows see further Section 15.3 and the
33 glossary. The issue of climate finance is closely related to the conversation on international cooperation
34 and the question of how cross-border investments can support climate mitigation and adaptation in
35 developing countries. However, the issue is also related to more general questions of how financial
36 institutions, both public and private, can assess climate risks and opportunities from all investments,
37 and what roles states, policy makers, regulators and markets can play in making them more sustainable.
38 In particular, the question of the respective roles of the public and private financial actors has become
39 important in deliberations on climate finance in recent years. The broader macroeconomic context is an
40 important starting point. Four major events and macro trends mark the developments in climate finance
41 in the previous five years and likely developments in the near-term.

- 42 • First, the 2015 Paris Agreement, with the engagement of the financial sector institutions in the
43 climate agenda has been followed by a series of related developments in financial regulation in
44 relation to climate change and in particular to the disclosure of climate related financial risk (*high*
45 *confidence*) (see Section 15.2.1).

- 1 • Second, the last five years have been characterised by a series of interconnected “headwinds” (see
2 Section 15.2.2), including rising private and public debt and policy uncertainty which work against
3 the objective of filling the climate investment gap (*high confidence*).
- 4 • Third, the 2020 COVID-19 pandemic crisis has put enormous additional strain on the global
5 economy, debt and the availability of finance, which will be longer-lasting (see Section 15.2.3). At
6 the same time, while it is still too early to draw positive conclusions, this crisis highlights
7 opportunities in terms of political and policy feasibility and behavioural change in respect of
8 realigning climate finance (*medium confidence*).
- 9 • Fourth, the sharp rise in global inequality and the effects of the pandemic have brought into renewed
10 sharp focus the need for a Just Transition (see Section 15.2.4) and a realignment of climate finance
11 and policies that would be beneficial for a new social compact towards a more sustainable world
12 that addresses energy equity and environmental justice (*high confidence*).

13

14 **15.2.1 Paris Agreement and the engagement of the financial sector in the climate agenda**

15 This is the first IPCC AR chapter on investment and finance since the 2015 Paris Agreement, which
16 represented a landmark event for climate finance because for the first time the key role of aligning
17 financial flows to climate goals was spelled out. Since then, the financial sector has recognised the
18 opportunity and has stepped up to centre-stage in the global policy conversation on climate change.
19 While before the Paris Agreement, only few financial professionals and regulators were acquainted with
20 climate change, today climate change is acknowledged as a strategic priority in most financial
21 institutions. This is a major change in the policy landscape from AR5. This is a major change in the
22 policy landscape from AR5. However, this does not mean that finance necessarily plays an adequate
23 enabling role for climate investments. On the contrary, the literature shows that without appropriate
24 conditions, finance can represent a barrier to fill the climate investment gap (Hafner et al. 2020). Indeed,
25 despite the enormous acceleration in policy initiatives (e.g. (NGFS 2020)) and coalitions of the willing
26 in the private sectors, the effect in terms of closing the investment gap identified already in AR5 has
27 been limited (see Section 15.5.2).

28 Financial investors have started to account for climate risk in some contexts but they do so only to a
29 limited extent (Monasterolo and de Angelis 2020; Alessi et al. 2021; Bolton and Kacperczyk 2021) and
30 the reasons for these remain unclear. Two aspects are relevant here. The first is the endogenous nature
31 of climate financial risk and opportunities (with the term “risk” meaning here the potential for adverse
32 financial impact whether, or not, the distribution of losses is known). Academics and practitioners in
33 finance are aware that financial risk can in certain contexts be endogenous, i.e., the materialization of
34 losses is affected by the action of financial players themselves. However, the standard treatment of risk
35 both in financial valuation models and in asset pricing assumes that risk is exogenous. In contrast,
36 endogeneity is a key feature of climate risk because today’s perception of climate risk affects climate
37 investment, which in turn affect directly the future risk. This endogeneity leads to the fact that multiple
38 and rather different mitigation scenarios are possible (see Chapter 3). Moreover, the likelihood of
39 occurrence of each alternative scenario is very hard to estimate. Further, the assessment of climate-
40 related financial risk requires to combine information related to mitigation scenarios as well as climate
41 impact scenarios, leaving open an important knowledge gap for the next years (see Section 15.6.1).

42 The second aspect is that the multiplicity of equilibria results in a coordination problem whereby the
43 majority of investors wait to move and reallocate their investments until they can follow a clear signal.
44 Despite the initial momentum of the Paris Agreement, for many investors, both public and private, the
45 policy signal seems not strong enough to induce them to align their investment portfolios to climate
46 goals.

1 Analyses of the dynamics of the low carbon transition suggest that it does not occur by itself and that it
2 requires a policy signal credible enough in the perception of market players and investors (Battiston et
3 al. 2021b). Credibility could require a policy commitment device (Brunner et al. 2012). The
4 commitment would also need to be large enough (analogous to the “whatever it takes” statement by the
5 European Central Bank during the 2011-12 European sovereign crisis (Kalinowski and Chenet 2020)).
6 In principle, public investments in low carbon infrastructures (or private-public partnerships) as well as
7 regulation could provide credible signals if their magnitude and time horizon are appropriate (past
8 experiences with FiTs models across countries provide useful lessons).
9

10 **15.2.2 Macroeconomic context**

11 Entering 2020, the world already faced large macroeconomic headwinds to meeting the climate finance
12 gap in the near-term – barring some globally coordinated action. While an understanding of the
13 disaggregated country-by-country, sector-by-sector, project-by-project, and instrument-by-instrument
14 approach to raising climate finances analysed in the later parts of this Chapter remains important,
15 macroeconomic drivers of finance remain crucial in the near-term.

16 Near-term finance financial flows in aggregate often show strong empirically observed cycles over time,
17 especially in terms of macroeconomic and financial cycles. By *near-term*, we mean here the likely cycle
18 over the next five to ten years (2020–2025 and 2020–2030), as influenced by global macroeconomic
19 real business cycles (output, investment and consumption), with periodic asymmetric downside impacts
20 and crises (Gertler and Kiyotaki 2010; Borio 2014; Jordà et al. 2017; Borio et al. 2018). Financial cycles
21 typically have strong co-movements (asset prices, credit growth, interest rates, leverage, risk factors,
22 market fear, macro-prudential and central bank policies) (Coeurdacier and Rey 2013). They have large
23 consequences for all types of financial flows such as equity, bond and banking credit markets, which in
24 turn are likely to impact climate finance flows to all sub-sectors and geographies (with greater expected
25 volatility in more risky and more leveraged regions). This is in contrast to *longer-term trend*
26 *considerations* (2020–2050) that typically focus the attention on drivers of disaggregated flows of
27 climate finance and policies. The upward trends of the cycles tend to favour speculative bubbles like
28 real estates at the expenses of investment in production and infrastructures whereas the asymmetric
29 downsides raise uncertainty and risks for longer-term investments on newer climate technologies, and
30 favour a flight to near-term safety (e.g., lowest risk non-climate short-term treasury investments, highest
31 creditworthy countries, and away from cross-border investments (see Section 15.5) – making the
32 challenge of longer-term low-carbon transition more difficult. In this respect, the impact of financial
33 regulation is unclear. On the one hand, it could be argued that the tighter bank regulations under Basel
34 III, combined with an economic environment with higher uncertainty and flatter yield curve, can push
35 banks to retrench from climate finance projects (Blended Finance Taskforce, 2018a), since banks tend
36 to limit loan maturity to 5 or 8 years, while infrastructure projects typically require the amortisation of
37 debt over 15-20 years (Arezki et al. 2016). On the other hand, other studies report that stricter capital
38 requirements are not a driving factor for moving away from sustainability projects (CISL and UNEP FI
39 2014)

40 Four key aspects of the global macroeconomy, each slightly different, pointed in a cascading fashion
41 towards a deteriorating environment for stepped-up climate financing over the next crucial decade
42 (2020–2030), even before COVID-19. The argument is often made that there is enough climate
43 financing available if the right projects and enabling policy actions (‘bankable projects’) present
44 themselves (Cuntz et al. 2017; Meltzer 2018). The attention to ‘bankability’ does not however address
45 access and equity issues (Bayliss and Van Waeyenberge 2018). Some significant gains in climate
46 financing at the sectoral and microeconomic level were nevertheless happening in specific segments,
47 such as solar energy financing and labelled green bonds (although how much of such labelled financing
48 is incremental to unlabelled financing that might have happened anyway remains uncertain) (Tolliver

1 et al. 2019). Issues of ‘labelling’ (Cornell 2020) apply even more to ESG (environmental, social and
2 governance) investments which started to grow rapidly after 2016 (see Section 15.6.6. for more details).
3 Overall, these increments for climate finance remained, however, small in aggregate relative to the size
4 of the shifts in climate financing required in the coming decade. Annual energy investments in
5 developing regions (other than China) which account for two-thirds of the world population, with least
6 costs of mitigation per ton of emissions (one-half that in developed regions), and for the bulk of future
7 expected global GHG emissions, saw a 20 percent decline in investments since 2016, and only a one-
8 fifth share of global clean energy investment, reflecting persistent financing problems and costs of
9 mobilizing finance towards clean energy transition, even prior to the pandemic (IEA 2021a). In the
10 words of a macroeconomic institution, ‘tangible policy responses to reduce greenhouse gas emissions
11 have been grossly insufficient to date’ (IMF 2020a). The reason is in part global macroeconomic
12 headwinds, which show a relative stagnation since 2016 and limited cross-border flows in particular
13 (Yeo 2019).

14 **Slowing and more unstable GDP growth.** The first headwind was more unstable and slowing GDP
15 growth at individual country levels and in aggregate because of worsening climate change impact events
16 (Donadelli et al. 2019; Kahn et al. 2019). As each warmer year keep producing more negative impacts
17 – arising from greater and rising variability and intensity of rainfall, floods, droughts, forest fires and
18 storms – the negative consequences have become more macro-economically significant, and worst for
19 the most climate-vulnerable developing countries (*high confidence*). Paradoxically, while these effects
20 should have raised the social returns and incentives to invest more in future climate mitigation, a
21 standard public policy argument, these macroeconomic shocks may work in the opposite direction for
22 private decisions by raising the financing costs now (Cherif and Hasanov 2018). With some climate
23 tipping points, potentially in the near-term reach (see Chapter 4: Future global climate: scenario-based
24 1 projections and near-term information in WGI) the uncertainty with regard to the economic viability
25 and growth prospects of selected macroeconomically critical sectors increases significantly (see
26 Chapter 8 and Chapter 17 in WGII). Taking account of other behavioural failures, this was creating a
27 barrier for pro-active and accelerated mitigation and adaptation action.

28 **Public finances.** The second headwind was rising public fiscal costs of mitigation and adapting to rising
29 climate shocks affecting many countries, which were negatively impacting public indebtedness and
30 country credit ratings (Cevik and Jalles 2020; Klusak et al. 2021) at a time of growing stresses on public
31 finances and debt (Benali et al. 2018; Kling et al. 2018; Kose et al. 2020) (*high confidence*). Every
32 climate shock and slowing growth puts greater pressures on public finances to offset these impacts.
33 Crucially, the negative consequences were typically greater at the lower end of income distributions
34 everywhere (Acevedo et al. 2018; Aggarwal 2019). As a result, the standard prescription of raising
35 distributionally adverse carbon taxes and reducing fossil fuel subsidies to raise resources faced political
36 pushback in several countries (Copland 2020; Green 2021), and low rates elsewhere. Reduced taxes on
37 capital, by contrast, was viewed as a way to improve growth (Bhattarai et al. 2018; Font et al. 2018),
38 and working against broader fiscal action. Progress with carbon pricing remained modest across 44
39 OECD and G20 countries, with 55-70% of all carbon emissions from energy use entirely unpriced as
40 of 2018 (OECD 2021a). Climate vulnerable countries meanwhile faced sharply rising cost of sovereign
41 debt. (Buhr et al. 2018). (Buhr et al. 2018) calculate the additional financing costs of Climate Vulnerable
42 Forum countries of 40 billion USD on government debt over the past 10 years and 62 billion USD for
43 the next 10 years. Including private financing cost the amount increases to 146–168 billion USD over
44 the next decade.

45 **Credit risks.** The third headwind is rising financial and insurance sector risks and stresses (distinct
46 from real ‘physical’ climate risks above) arising from the impacts of climate change, and systematically
47 affecting both national and international financial institutions and raising their credit risks (Dafermos
48 et al. 2018; Rudebusch 2019; Battiston et al. 2021a) (*high confidence*). Central banks are beginning to
49 take notice (Carney 2019; NGFS 2019). It is also the case that, even if at greater risk from stranded

1 assets in the future, the large-scale financing of new fossil fuel projects by large global financial
2 institutions rose significantly since 2016, because of perceived lower private risks and higher private
3 returns in these investments and other factors than in alternative but perceived more risky low carbon
4 investments.

5 **Global growth.** The fourth headwind entering 2020 was the sharply slowing global macroeconomic
6 growth, and prospects for near-term recession (which occurred in the pandemic). During global real
7 and financial cycle downturns (Jordà et al. 2019), the perception of general financial risk rises, causing
8 financial institutions and savers to reallocate their financing to risk-free global assets (*high confidence*).
9 This ‘flight to safety’ was evident even before the recent pandemic, marked by an extraordinary tripling
10 of financial assets to about 16.5 trillion USD in negative-interest earning ‘safer’ assets in 2019 in world
11 debt markets – enough to have nearly closed the total financing gap in climate finance over a decade.

12

13 **15.2.3 Impact of COVID-19 pandemic**

14 The macroeconomic headwinds have worsened dramatically with the onset of COVID-19. Almost two
15 years after the pandemic started, it is still too uncertain and early to conclude impacts of the pandemic
16 until 2025-2030, especially as they affect climate finance. Multiple waves of the pandemic, new virus
17 mutations, accumulating human toll, and growing vaccine coverage but vastly differing access across
18 developed versus developing regions are evident. They are causing divergent impacts across sectors
19 and countries, which combined with the divergent ability of countries and regions to mount sufficient
20 fiscal and monetary policy actions imply continued high uncertainty on the economic recovery paths
21 from the crisis. The situation remains more precarious in middle and low-income developing countries
22 (IMF 2021a). While recovery is happening, the job losses have been large, poverty rates have climbed,
23 public health systems are suffering long-term consequences, education gains have been set back, public
24 debt levels are higher (5-10% of GDP higher), financial institutions have come under longer-term stress,
25 a larger number of developing countries are facing debt distress, and many key high-contact sectors
26 such as tourism and trade will take time to recover (Eichengreen et al. 2021). The implication is
27 negative headwinds for climate finance with public attention focused on pandemic relief and recovery
28 and limited (and divergent) fiscal headroom for a low carbon transition, with considerable uncertainties
29 ahead (Hepburn et al. 2020b; Maffettone and Oldani 2020; Steffen et al. 2020).

30 The larger and still open public policy choice question that COVID-19 now raises is whether there is
31 room for public policy globally and in respect of their individual economies to integrate climate more
32 centrally to their growth, jobs and sustainable development strategies worldwide for ecological and
33 economic survival. The outcomes will depend on the robustness of recovery from the pandemic, and
34 the still evolving public policy responses to the climate agenda in the recovery process. Private equity
35 and asset markets have recovered surprisingly rapidly during the pandemic (in response to the massive
36 fiscal and central bank actions generating large excess savings with very low or negative yields boosting
37 stock markets). On public spending, some early studies suggest that the immediate economic recovery
38 packages were falling well short of being sufficiently climate sustainable (Gosens and Jotzo 2020;
39 Kuzemko et al. 2020; O’Callaghan 2021) but several governments have also announced intentions to
40 spend more on a green recovery, a ‘build back better’ and Just Transition efforts (see Section 15.2.4),
41 although outcomes remain highly uncertain (Lehmann et al. 2021; Markandya et al. 2021).

42 An important immediate finding from the COVID-19 crisis was that the slowdown in economic activity
43 is illustrating some of these choices: immediately after the onset, more costly and carbon-intensive coal
44 use for energy use tumbled in major countries such as China and the USA, while the forced ‘stay-at-
45 home’ policies adopted around the major economies of the world led to a -30-35% decline in individual
46 country GDP, and was in turn been associated with a decrease in daily global CO₂ emissions by -26%
47 at their peak in individual countries, and -17% globally (-11 to -25% for $\pm 1\sigma$) by early April 2020

1 compared with the mean 2019 levels, with just under half coming from changes in surface transport,
2 city congestion and country mobility (Le Quéré et al. 2020). Along with the carbon emissions drop was
3 a dramatic improvement in other parameters such as clean air quality. Moreover, longer-term
4 behavioural impacts are also possible: a dramatic acceleration of digital technologies in
5 communications, travel, retail trade and transport. The question however is whether the world might
6 revert to the earlier carbon-intensive path of recovery, or to a different future, and the choice of policies
7 in shaping this future. Studies generally suggest that the gains from long-term impacts of the pandemic
8 on future global warming will be limited and depend more on the nature of public policy actions and
9 long-term commitments by countries to raise their ambitions, not just on climate but on sustainable
10 development broadly (Barbier 2020; Barbier and Burgess 2020; Forster et al. 2020; Gillingham et al.
11 2020; Reilly et al. 2021). The positive lesson is clear: opportunities exist for accelerating structural
12 change, and for a re-orientation of economic activity modes to a low-carbon use strategy in areas such
13 as coal use in energy consumption and surface transport, city congestion and in-country mobility, for
14 which lower-cost alternatives exist and offer potentially dramatic gains (Hepburn et al. 2020b).

15 A new consensus and compact towards such a structural change and economic stimulus instruments
16 may therefore need to be redrawn worldwide, where an accelerated low carbon transition is a priority;
17 and accelerated climate finance to spur these investments may gain by becoming fully and rapidly
18 integrated with near-term economic stimulus, growth and macroeconomic strategies for governments,
19 central banks, and private financial systems alike. If that were to happen, COVID-19 may well be a
20 turning point for sustainable climate policy and financing. Absent that, a return to ‘business-as-usual’
21 modes will mean a likely down-cycle in climate financing and investments in the near-term.

22 Expectations that the recovery package stimulus will increase economic activity rely on the assumption
23 that increased credit investment will have a positive effect on demand, the so-called demand-led
24 policy (Mercure et al. 2019). The argument for a green recovery also draws on the experience from the
25 post Global Financial Crisis in 2008–2009 (GFC) recovery, in which large economies such as China,
26 South Korea, the US and the EU observed that green investments propelled the development of new
27 industrial sectors. Noticeably, this had a positive net effect on job creation when compared to the
28 investment in traditional infrastructure (UKERC 2014; Vona et al. 2018; Jaeger et al. 2020). For a more
29 in-depth discussion on macroeconomic-finance possible response see Section 15.6.3. Here, we conclude
30 with the options for reviving a better globally coordinated macroeconomic climate action. The options
31 are some combinations of five possible elements:

32 (a) Reaffirmation of a strong financial agenda in future Conference of Parties’ meetings, and a new
33 collective finance target, which will need to be undertaken by 2025. Given that the shortfalls in
34 financing are likely to be acute for developing regions and especially the more debt-stressed and
35 vulnerable (Dibley et al. 2021; Elkhishin and Mohieldin 2021; Laskaridis 2021; Umar et al. 2021),
36 developed countries may wish to step up their collective support (Resano and Gallego 2021). One
37 possibility is to expedite the new SDR issuance allocation rules for the 650 billion USD recently (2021)
38 approved, most of which will go to increase the reserves of G-7 and other High-Income countries unless
39 voluntarily reallocated towards the needs of the most vulnerable low-income countries, raising
40 resources potentially ‘larger than the Marshall Plan in today’s money’ (IMF 2021b; Jensen 2021;
41 Obstfeld and Truman 2021), with decisions to be taken (Ameli et al. 2021a) note the climate investment
42 trap of current high cost of finance that effectively lowers green electricity production possibilities in
43 Africa for a cost optimal pathway. Other initiatives could also include G-7 and G-20 governments
44 (especially with the lead taken by the developed members for cross-border support to avoid over-
45 burdening public resources in developing countries) running coordinated fiscal deficits to accelerate the
46 financing of low carbon investments (‘green fiscal stimulus’).

47 (b) introducing new actions, including regulatory, to take some of the risks off-the-table from
48 institutional financial players investing in climate mitigation investment and insurance. This could

1 include the provision of larger sovereign guarantees to such private finance, primarily from developed
2 countries but jointly with developing countries to create a level-playing field (Dafermos et al. 2021)
3 backed by explicit and transparent recognition of the ‘social value of mitigation actions’ or SVMAs, as
4 fiscally superior (because of bigger ‘multipliers’ of such fiscal action to catalyse private investment
5 than direct public investment) and the bigger social value of such investments (Article 108, UNFCCC)
6 (Hourcade et al. 2018; Krogstrup and Oman 2019).

7 (c) facilitating and incentivizing much larger flows of cross-border climate financing which is especially
8 crucial for such investments to happen in developing regions, where as much as two-thirds of collective
9 investment may need to happen (IEA 2021a), and where the role of multilateral, regional and global
10 institutions such as the IMF (including the expansion in availability of climate SDRs referred earlier)
11 could be important.

12 (d) global central banks acting in coordination to include climate finance as intrinsic part of their
13 monetary policy and stimulus (Carney 2019; Jordà et al. 2019; Hilmi et al. 2021; Schoenmaker 2021;
14 Svartzman et al. 2021)

15 (e) an acceleration of Just Transition initiatives, outlined further below (Section 15.2.4).

16

17 **15.2.4 Climate Finance and Just Transition**

18 Climate finance in support of a Just Transition is likely to be a key to a successful low-carbon transition
19 globally (*high confidence*). Ambitious global climate agreements are likely to work far better by
20 maximising cooperative arrangements (IPCC 2018; Gazzotti et al. 2021) with greater financing support
21 from developed to developing regions in recognition of ‘common but differentiated responsibilities and
22 respective capabilities’ and a greater ethical sense of climate justice (Khan et al. 2020; Sardo 2020;
23 Warner 2020; Pearson et al. 2021). While Just Transition issues apply within developed countries as
24 well (see later discussion), these are of relatively second-order significance to addressing climate justice
25 issues between richer and poorer countries – given the scale of financing and existing social safety nets
26 in the former and their absence in the latter. For example, over the past three decades drought in Africa
27 has caused more climate-related mortality than all climate-related events combined from the rest of the
28 world (Warner 2020). These issues can however serve both as a bridge and a barrier to greater
29 cooperation on climate change. The key is to build greater mutual trust with clearer commitments and
30 well-structured key decisions and instruments (Sardo 2020; Pearson et al. 2021).

31 The Just Transition discussion has picked up steam. It was explicitly recognised in the Paris Agreement
32 and the 2018 Just Transition Declaration signed by 53 countries at COP24, which ‘recognised the need
33 to factor in the needs of workers and communities to build public support for a rapid shift to a zero-
34 carbon economy.’ Originally proposed by global trade unions in the 1980s, the recent discourse has
35 become broader. It has coalesced into a more inclusive process to reduce inequality across all three
36 areas of energy, environment and climate (McCauley and Heffron 2018; Bainton et al. 2021). It seeks
37 accelerated public policy support to ensure environmental sustainability, decent work, social inclusion
38 and poverty eradication (Burrow 2017), widely shared benefits, and protection of indigenous rights, and
39 livelihoods of communities and workers who stand to lose (including workers in fossil fuel sectors such
40 as coal and oil and gas) (UNFCCC 2018b; EBRD 2020; Jenkins et al. 2020). Because the process
41 involves ‘climate justice’ and equity within and across generations, it involves difficult political trade-
42 offs (Newell and Mulvaney 2013). The implications for a Just Transition in climate finance are clear:
43 expanding equitable and greater access to climate finance for vulnerable countries, communities and
44 sectors, not just for the most profitable private investment opportunities, and a larger role for public
45 finance in fulfilling existing finance commitments (Bracking and Leffel 2021; Kuhl 2021; Long 2021;
46 Roberts et al. 2021) .

1 Large shocks, such as pandemics and slow-growing one such as climate are typically known to worsen
2 inequality (IMF and World Bank 2020). Evidence from 133 countries between 2001–2018 suggests that
3 such shocks can cause social unrest, and migration pressures, especially when starting inequality is high
4 and social transfers are low (Saadi Sedik and Xu 2020). Additionally, climate policies are more
5 politically difficult to implement, when the setting is one of high inequality but much less politically
6 costly where incomes are more evenly distributed with stronger social safety nets (Furceri et al. 2021).
7 A redrawn social compact incorporating climate (Beck et al. 2021) that would adopt redistributive taxes
8 and lower carbon consumption, and strengthen state capacity to deliver safety nets, health, education
9 with accelerated climate and environmental sustainability within and across countries is increasingly
10 recognised as important. Countries, regions and coordination bodies of the larger countries (G-7, G-20)
11 have already begun such as shift to financing of a Just Transition, but primarily focused on the
12 developed countries, although gaps remain (Krawchenko and Gordon 2021).

13 Such a redrawing of a social compact has happened significantly in the past, for example, after the
14 1860s ‘gilded age of capital’ with the enlargement of the franchise in democratization waves in Europe
15 and the Americas (Dasgupta and Zibblatt 2015, 2016). Not only was social conflict avoided but growth
16 outcomes became more equitable and faster. Similarly, comprehensive modern social safety nets and
17 progressive taxation, which started in the Great Depression and was extended in the post-war period,
18 had both a positive pro-growth and lower inequality effects (Brida et al. 2020).

19 There are three levels of at which policy attention on climate financing now may need to be focused.
20 The first is the need for to addressing the global equity issues in climate finance in a more carefully
21 constructed globally cooperative public policy approach. The second is to address issues appropriately
22 with enhanced support, at the national level. The third is to work it down further, to addressing needs
23 at local community levels. Because private investors and financing mostly deal with allocation to
24 climate finance at a global portfolio level, then to allocation by countries, and finally to individual
25 projects, the challenge for them is to refocus attention to Just Transition issues at the country level, but
26 also globally as well as locally (in other words, at all three levels).

27 Climate finance will likely face greater challenges in the post-pandemic context (Hanna et al. 2020;
28 Henry et al. 2020). Evidence from COVID-19 pandemic suggests that those in greatest vulnerability
29 often had the least access to human, physical, and financial resources (Ruger and Horton 2020). It has
30 also left in its wake divergent prospects for economic recovery, with rising constraints on credit
31 ratings and costly debt burden in many developing countries contrasted with the exceptionally low
32 interest rate settings in developed economies driving the limited fiscal space in the former groups
33 (Benmelech and Tzur-Ilan 2020). Similarly, monetary policies are likely to be much tighter in
34 developing countries in part structurally because of the absence of ‘exceptional privilege’ of global
35 reserve currencies in developed economies.

36 The result is a divergence in recovery prospects in the aftermath of the pandemic, with output losses
37 (compared to potential) set to worsen in developing economies (excluding China) as compared to
38 developed countries (IMF 2020b). In these circumstances, a coordinated and cooperative approach,
39 instead of unilateralism, might work better (McKibbin and Vines 2020). In the case of climate,
40 simulations clearly suggest the need and advantages of better coordinated climate action with stepped-
41 up Paris Agreement envisaged transfers (IMF 2020b). Several options in international climate finance
42 arrangements to support a Just Transition are both available and urgent.

43 As a first priority, measures might need to accelerate a mix of equitable financial grants, low-interest
44 loans, guarantees and workable business models access across countries and borders, from developed
45 countries to in low-income countries. A big push on low-carbon energy access globally, especially in
46 large low-income regions such as Africa, with accelerated financial transfers makes sense (Boamah
47 2020). For about one billion people globally at the base of the pyramid without access to modern low-
48 carbon energy access, such an action, with enormous immediate leap-frogging potential, would be a

1 key pathway to achieve the SDGs, ensure that high-carbon energy use is avoided, such as the burning
2 of biomass and forests for charcoal, and improve air quality and public health, especially women's
3 health (van der Zwaan et al. 2018; Nathwani and Kammen 2019; Dalla Longa and van der Zwaan 2021;
4 Michaelowa et al. 2021; Osabuohien et al. 2021).

5 A second priority is to accelerate the implementation of the 100 billion USD a year (and likely more
6 given growing financing gaps) in climate finance commitments expressed in the Copenhagen
7 Agreement Accord (and reiterated since) from developed to developing countries, and to build greater
8 confidence by agreeing rapidly on key definitions. Shifting to a grant equivalent net flows definition
9 of climate finance, which is now universally accepted for all other aid flows by all parties since 2014
10 and which took effect since 2019 on every other public international good finance provision (under the
11 SDGs), with the sole exception of climate finance, would resolve many uncertainties: the disbursement
12 of climate finance flows on a grant equivalent basis that is comparable across institutions, instruments
13 and countries, and measurement with greater accuracy about the effective transfer of resources. The
14 journey to get to a clear and precise definition of net Official Overseas Development Assistance (ODA)
15 took time. The original proposal was first initiated in the 1960s (Pincus 1963) but it was not till MDB's
16 and others laid out the compelling reasons why (Chang et al. 1998) that this was accomplished:
17 especially to resolve decades of confusion and inconsistency between different types of financial flows
18 and hence the perennial measurement problems and 'the compromise between political expediency and
19 statistical reality' (Bulow and Rogoff 2005; Hynes and Scott 2013; Scott 2015, 2017).

20 A third related and increasingly crucial priority is to expedite the operational definition of blended
21 finance and promote the use of public guarantee instruments. Private flows to accelerate the low-carbon
22 transition in developing countries would benefit enormously, by gaining clearer access to public
23 international funds and support defined on a grant equivalent basis, provided development and climate
24 finance operational definitions and procedures were improved on an urgent basis (Blended Finance
25 Taskforce 2018a; OECD-DAC 2021). When blended and supported by public finance and policy, the
26 grant equivalency measure can easily and more accurately measure the value and benefit of blended
27 public and private finance by comparing the effective interest cost (and volume) gain with such
28 financing, against the benchmark costs without such blending. Here again, a pressing challenge is to
29 improve the operational definitions of what counts as ODA within blended finance. Blended finance
30 remains very poorly defined and accounted (Pereira 2017; Andersen et al. 2019; Attridge and Engen
31 2019; Basile and Dutra 2019). Guarantees are expressly not included in the definition of ODA (Garbacz
32 et al. 2021). As a result, bilateral and multilateral agencies have no incentive or limited authority and
33 basis to use such instruments, while multilateral development banks continue to approach guarantees
34 with great caution because of the limits of their original charters (World Bank 2009) and require
35 counter-indemnities by recipient countries, internal and historic agency inertia, perceived loss of control
36 over the use of funds (compared to their preferred direct project-based lending) and employ restrictive
37 accounting rules for capital provisioning of guarantees at 100% of their face value to maintain AAA
38 ratings with credit rating agencies (Humphrey 2017; Pereira dos Santos and Kearney 2018a; Bandura
39 and Ramanujam 2019; Hourcade et al. 2021a). Largely because of such official uncertainty the actual
40 flows of blended finance and guarantees continue to remain a very small share (typically, less than 5%)
41 of official and multilateral finance flows to lower project risks and costs, and hence the potential for
42 large-scale accelerated low-carbon private investments in developing countries. Public guarantees can
43 offer a fifteen times multiplier effect on the scale of low-carbon investments generated with such
44 support, compared to a 1:1 ratio in direct financing (Hourcade et al. 2021a).

45 It makes sense to expedite these operational procedures (Khan et al. 2020) which cannot be otherwise
46 explained except in terms of avoiding responsibilities, even where the benefits would be high (Klöß et
47 al. 2018). It also causes (unnecessary) fragmentation and complexity and often 'strategic' ambiguity by
48 many actors (Pickering et al. 2017), which worsens the possibilities for international cooperation, a
49 critical requirement to achieve the Paris goals (IPCC 2018). The world would gain collectively if these

1 issues were to be decided soon. The absence of such a collective decision continues to be exceptionally
2 costly for the implementation of the Paris Agreement because of the fractious and seemingly insoluble
3 negotiating climate and a breakdown of trust that this has created (Roberts and Weikmans 2017).

4 A fourth priority is on expanding jobs and dealing with job losses in the global low carbon transition
5 (Carley and Konisky 2020; Crowe and Li 2020; Pai et al. 2020; Cunningham and Schmillen 2021;
6 Hanto et al. 2021), especially in coal and other sectors, as well as land and other effects for indigenous
7 communities (Zografos and Robbins 2020). Many countries, especially low-income countries, remain
8 dependent on fossil fuels for their energy and exports and jobs, and support for their transition to a low-
9 carbon future will be essential. Global recovery from the pandemic will take longer than initially
10 envisaged (IMF 2021c; OECD 2021b) and an accelerated climate action for a Build Back Better global
11 infrastructure plan with better and more resilient jobs might play a key role as part of the Just
12 Transitions. Already, there is substantial evidence (Sulich et al. 2020; Dell'Anna 2021; Dordmond et
13 al. 2021) that a more sustainable climate path would generate many more net productive jobs (with
14 much higher employment multipliers and mutual gains from given spending) than would any other
15 large-scale alternative. But this would nevertheless require a carefully managed transition globally,
16 including access to much larger volumes of climate financing in developing economies (Muttitt and
17 Kartha 2020). The multilateral finance institutions have generally played a supportive role, expanding
18 their financing to developing countries during the pandemic (even as bilateral aid flows have fallen
19 sharply), but have been hampered by the of constraints on their mandates and instruments (as noted
20 earlier). Political leadership and direction will be again crucial to enhance their roles. The recent
21 expansion of SDR quotas at the IMF similarly might help, but the current distributions of quota benefits
22 flow primarily to the developed countries and does little to expand investment flows on a longer-term
23 basis for a global expansion in growth and job opportunities in the low-carbon transition.

24 As a fifth priority, transformative climate financing options based on equity and global sustainability
25 objectives may also need to consider a greater mix of public pricing and taxation options on the
26 consumption side (Arrow et al. 2004; Folke et al. 2021). Two-thirds of global GHG emissions directly
27 or indirectly are linked to household consumption, with average per capita carbon footprint of North
28 America and Europe of 13.4 and 7.5 tCO₂-eq/capita, respectively, compared to 1.7 in Africa and Middle
29 East (Gough 2020) and as high as 200tCO₂-eq/capita among the top 1% in some high-income
30 geographies versus 0.1tCO₂-eq at the other end of the income distribution in some least-developed
31 countries (Chancel and Piketty 2015). Globally, the highest-expenditure households account for eleven
32 times the per capita emissions of lowest-expenditure households, with rising carbon income elasticities
33 that suggest 'redistribution of carbon shares from global elites to global poor' as welfare efficient
34 (Chancel and Piketty 2015; Hubacek et al. 2017). Within countries and regions, and within sectors,
35 similar patterns hold. The top 10% of the population with the highest per capita footprints account for
36 27% of the EU carbon footprint, and the top 1% have a carbon footprint of 55tCO₂-eq/cap, with air
37 transport the most elastic, unequal and carbon-intensive consumption (Ivanova and Wood 2020).
38 Similarly, within sectors, there are large differences in carbon-intensity in the building sector in North
39 America (Goldstein et al. 2020) and across cities where consumption-based GHG emissions vary widely
40 across the world (ranging from 1.8 to 25.9 tCO₂-eq/capita).

41 Numerous options exist (Broeks et al. 2020; Nyfors et al. 2020) for such carbon consumption reduction
42 measures, while potentially improving societal well-being, for example: (a) inner-city zoning
43 restrictions on private cars and promoting walking/bicycle use and improved shared low-carbon
44 transport infrastructure; (b) advertising regulation and carbon taxes and fees on high-carbon luxury
45 status goods and services; (c) subsidies and exemptions for low-carbon options, higher value-added
46 taxes on specific high-carbon products and services, subsidies for public low-carbon options such as
47 commuter transport, and other behavioural nudges (Reisch et al. 2021); and (d) framing options
48 (emphasizing total cost of car over life-times), mandatory smart metering, collective goods and services
49 (leasing, renting, sharing options) and others. Finally, reducing subsidies on fossil fuels, raising the

1 progressivity of taxes and raising overall wealth taxes on the richest households, which has been sharply
2 falling (Scheuer and Slemrod 2021) even as global income and wealth has risen with regressive and
3 falling overall taxes (Alvaredo et al. 2020; Saez and Zucman 2020) could effectively generate
4 significant revenues (over 1% of GDP yr⁻¹, about the same size as the proposed global 50 USD per ton
5 carbon price proposed and estimated by the IMF/OECD 2021 report to G20 (IMF and OECD 2021) to
6 cover expected net interest costs on overall decarbonization initiatives and financing of green new deals
7 (Schroeder 2021).

8 These five options identified above on near-term actions and priorities will however, require greater
9 collective political leadership. A review of past crisis episodes suggests that collective actions to avoid
10 large global or multi-country risks work well primarily when the problems are well-defined, a small
11 number of actors are involved, solutions are relatively well-established scientifically, and public costs
12 to address them are relatively small (Sandler 1998, 2015) (for example, dealing with early pandemic
13 outbreaks such as Ebola, TB, and cholera; extending global vaccination programs such as smallpox,
14 measles and polio; early warning systems and actions such as tsunamis, hurricanes/cyclones and
15 volcanic disasters; Montreal Protocol for ozone depleting refrigerants, and renewables wind and solar
16 energy development). They but do not appear to work as well for more complex global collective action
17 problems which concern a number of economic actors, sectors, without inexpensive and mature
18 technological options, and where political and institutional governance is fragmented. Greater political
19 coordination is needed because the impacts are often not near-term or imminent, but diffuse, slow-
20 moving and long-term, and where preventive disaster avoidance is costly even when these costs are low
21 compared to the longer-term damages—till tipping points are reached of the need for reduced ‘stressors’
22 and increasing ‘facilitators’ (Jagers et al. 2020). But by then, it may be too late.

23 Private institutional investors equally might equally wish to pay greater attention to the Just Transition
24 finance issues. It would be useful for investors to identify ways to support to such initiatives, and more
25 clearly identifying the benefits of such transition measures envisaged by both countries and investment
26 financing proposals, including incorporating Just Transition consideration in their support to broader
27 ESG (environmental, social and governance) and green financing initiatives.

28 The second level of attention needed on Just Transitions has to do with inequities within a large country
29 setting, developed or developing. The Just Transition issue exists within developed countries as well.
30 As the ongoing pandemic illustrates, the first climate burden hit is often felt most acutely at the level of
31 states and cities, with many smaller ones without enough fiscal capacity or ability to mount an adequate
32 discretionary counter policy. Only national governments have ability to borrow more in their fiscal
33 accounts to address large collective problems, whether pandemics or climate change. Therefore, it is
34 important that national policies and funds be available for programs to address the Just Transition issues
35 for larger sub-national states, cities and regions. This would be helped by countries including Just
36 Transition initiatives in their NDCs for financing (as South Africa has recently done), and attention by
37 external financing agencies and MDBs to large-scale adverse impacts in their climate policies and
38 investments. For example, the EU Green Deal plans (Nae and Panie 2021) includes several initiatives
39 (focusing on industries, regions and workers adversely affected with explicit programs to address them).

40 The third level of argument is for a shift in focus from an exclusive attention to financing of mitigation
41 and low-carbon new investments projects to also better understanding and addressing the local adverse
42 impacts of climate change on communities and people, who are vulnerable and increasingly
43 dispossessed due to losses and damages from climate change or even those who are impacted by de-
44 carbonization measures in the fossil fuel sectors, transportation, as well as those who are harmed by
45 polluting sectors: indigenous men and women, minorities and generally the poor. It is evident that very
46 few resources are available to countries, investors, civil society, and smaller development institutions
47 seeking to achieve a just transition (Robins and Rydge 2020).

1 Finally, greater support is warranted for smaller towns and cities, local networks, SMEs, communities,
 2 local authorities and universities for projects, research ideas and proposals (Lubell and Morrison 2021;
 3 Moftakhari et al. 2021; Stehle 2021; Vedeld et al. 2021).

4

5 **15.3 Assessment of current financial flows**

6 **15.3.1 Financial flows and stocks: orders of magnitude**

7 Assessments of finance for climate action need to be placed within the broader perspective of all
 8 investments and financing flows and stocks. This section provides aggregate level reference points of
 9 relevance to the remainder of this Chapter, notably when assessing current levels of climate and fossil
 10 fuel-related investments and financing (Sections 15.3.2.3 and 15.3.2.4 respectively), as well as
 11 estimates investment and financing needed to meet climate objectives (Section 15.4).

12 Measures of financial flows and stocks provide complementary and interrelated insights into trends over
 13 time: the accumulation of flows, measured per unit of time, results in stocks, observed at a given point
 14 in time (IMF 2009; UN and ECB 2015). On the flows side, GDP, a System of National Accounts (SNA)
 15 statistical standard that measures the monetary value of final goods and services produced in a country
 16 in a given period of time. In 2020, global GDP represented above 70 trillion USD₂₀₁₅ (down from almost
 17 80 trillion USD in 2019), out of which developed countries represented approx. 60% (Figure 15.1); a
 18 slowly decreasing share over the last years. The GDP metric is useful here as an indicator of the level
 19 of activity of an economy but gives no indication relating to human wellbeing or SDG achievements
 20 (Giannetti et al. 2015) counts positively activities that negatively impact the environment, without
 21 making deductions for the depletion and degradation of natural resources.

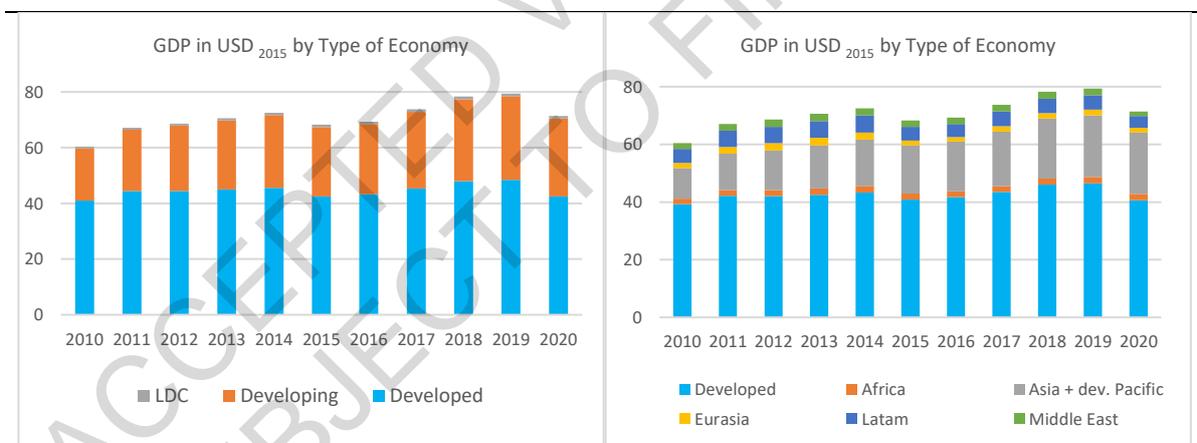

Figure 15.1 Financial flows – GDP (USD₂₀₁₅ tr.) by Type of Economy (left) and Region (right)

Note: Regional breakdown based on official UN country classification. GDP in USD₂₀₁₅ trillion. Source: World Bank Data (2020a). Numbers represent aggregated country data. Last updated data on 15 September 2021. CC BY-4.0

22

23 Gross-fixed capital formation (GFCF), another SNA standard that covers tangible assets (notably
 24 infrastructure and equipment) and intangible assets, is a good proxy for investment flows in the real
 25 economy. In 2019, global GFCF reached 23 trillion USD compared to 16.2 trillion USD in 2010, a 42%
 26 increase (Figure 15.2). Global GFCF represents about a quarter of global GDP, a relatively stable ratio
 27 since 2008. This share is, however, much higher for emerging economies, notably in Asia, which are
 28 building new infrastructure at scale. As analysed in Sections 15.4 and 15.5, infrastructure investment
 29 needs and gaps in developing countries are significant. How these are met over the next decade will
 30 critically influence the likelihood of reaching the Paris Agreement goals.

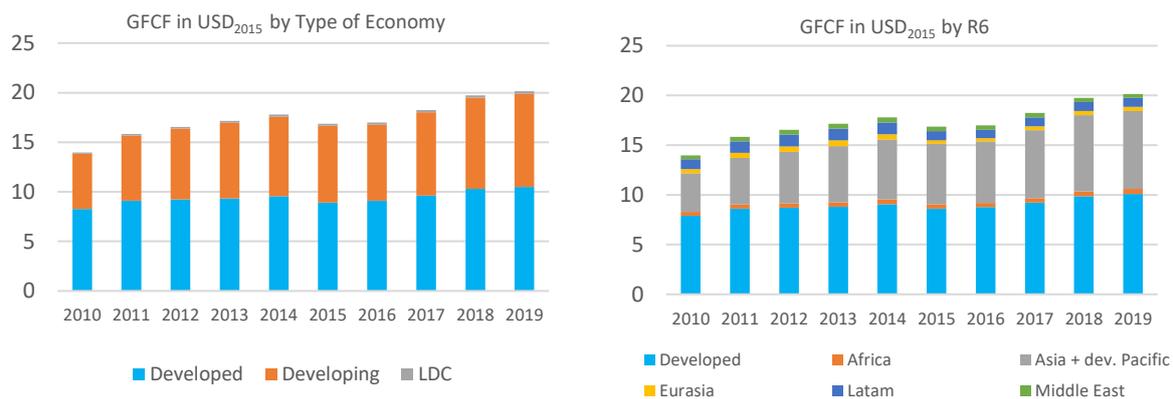

Figure 15.2 Financial flows – GFCF (USD₂₀₁₅ tr.) by Type of Economy (left) and Region (right)

Note: Regional breakdown based on official UN country classification. GDP in constant 2015 USD trillion USD₂₀₁₅. Gross fixed capital formation (GFCF) includes land improvements (fences, ditches, drains, and so on); plant, machinery, and equipment purchases; and the construction of roads, railways, and the like, including schools, offices, hospitals, private residential dwellings, and commercial and industrial buildings. Source: World Bank Data (2020b). Data for 2020 not available. Last updated Data 15 September 2021. CC BY-4.0

1 One the stock side, an increasingly significant portion of the growing value of financial capital (stocks
 2 in particular) may be disconnected from the value of underlying productive capital in real economy
 3 (Igan et al. 2020). This trend, however, remains uneven between developed countries, most of which
 4 have relatively deep capital markets, and developing countries at different stages of development
 5 (Section 15.6.7). Bonds, a form of debt financing, represent a significant share of total financial assets.
 6 As of August 2020, the overall size of the global bond markets (amount outstanding) was estimated at
 7 approximately 128.3 trillion USD, out of which over two thirds from “supranational, sovereign, and
 8 agencies”, and just under a third from corporations (ICMA 2020b). As discussed later in the Chapter,
 9 since AR5, an increasing number and volume of bonds have been earmarked for climate action but
 10 these still only represent less than 1% of the total bond market. As of end 2020, climate aligned bonds
 11 outstanding were estimated at 0.9 trillion (Giorgi and Michetti 2021), though already raising concerns
 12 in terms of both underlying definitions (Section 15.6.6) and risks of increased climate-related
 13 indebtedness (Section 15.6.1, 15.6.3).

14 From the perspective of climate change action, these orders of magnitude make it possible to highlight
 15 the relatively small size of current climate finance flows and relatively larger size of remaining fossil
 16 fuel-related finance flows (discussed in the following two sub-sections), as well as, more generally, the
 17 significant overall scale of financial flows and stocks that have to be made consistent with climate goals.
 18 These orders of magnitude further make it possible to put in perspective climate-related investment
 19 needs (Section 15.4) and gaps (Section 15.5).

20

21 15.3.2 Estimates of climate finance flows

22 The measurement of climate finance flows continues to face similar definitional, coverage and
 23 reliability issues than at the time of AR5 and special report on the impacts of global warming of 1.5°C,
 24 despite progress made (more sources, greater frequency, and some definitional improvements) by a
 25 range of data providers and collators. Based on available estimates (Table 1 and Figure 3), flows of
 26 annual global climate finance are on an upward trend since AR5, reaching a high-bound estimate of 681
 27 billion USD in 2016 (UNFCCC 2018a). Latest available estimates, indicate a drop in 2018 (Buchner et
 28 al. 2019) and a rebound in 2019 and 2020 (Naran et al. 2021) (*medium confidence*). Although not
 29 directly comparable in terms of scope, current climate finance flows remain small (approx. 3%)

1 compared to the GFCF reference point introduced in Section 15.3.1, as well as needs to be put in
 2 perspective with remaining fossil fuel financing (see Section 15.3.2.3) (*medium confidence*).

Table 15.1 Total climate finance flows between 2013 and 2020

Source (type)	2013	2014	2015	2016	2017	2018	2019	2020
UNFCCC SCF (total high)	687	584	680	681	Published after lit. cut-off		n/a	n/a
UNFCCC SCF (total low / CPI)	339	392	472	456	/608	/540	/623	/640

Note: Given the variations in numbers reported by different entities, changes in data, definitions and methodologies over time, there is low confidence attached to the aggregate numbers presented here. The higher bound reported in the SCF’s Biennial Assessment reports includes estimates from the International Energy Agency on energy efficiency investments, which are excluded from the lower bound and CPI’s estimates. Source: (UNFCCC 2018a; Buchner et al. 2019; Naran et al. 2021).

Non-energy GHG reductions, Coastal protection. Source: Own calculations, based on (Naran et al. 2021).

4
 5 At an aggregate level, in both developed and developing countries, the vast majority of tracked climate
 6 finance is sourced from domestic or national markets rather than cross-border financing (Buchner et al.
 7 2019). This reinforces the point that national policies and settings remain crucial (Section 15.6.2), along
 8 with the development of local capital markets (Section 15.6.7).

9 Climate finance in developing countries remains heavily concentrated in a few large economies (*high*
 10 *confidence*), with Brazil, India, China and South Africa accounting for 25% to 43% depending on the
 11 year, a share similar to that represented by developed countries. Least-developed countries (LDCs), on
 12 the other hand, continue to represent less than 5% year-on-year (BNEF 2019; Buchner et al. 2019)

1 (*medium confidence*). Further, the relatively modest growth of climate finance in developed countries
2 is a matter of concern given that economic circumstances are, in most cases, relatively more amenable
3 to greater financing, savings and affordability than in developing countries.

4 At a global level, the majority of tracked climate finance is assessed as coming from private actors
5 (Buchner et al. 2019), although, as discussed in Box 15.2, the boundaries between private and public
6 finance include significant grey zones, which implies that different definitions could lead to different
7 conclusions (for instance see (Yeo 2019; Weikmans and Roberts 2019)). However, private investments
8 in climate projects and activities often benefit from public support in the form of co-financing,
9 guarantees or fiscal measures. In terms of financial instruments and mechanisms, debt as well as balance
10 sheet financing (which can rely on both own resources and further debt) and project financing
11 (combining a large debt portion and smaller equity portion) represent the lion's share. In this context,
12 the rapid rise of climate-related bond issuances since AR5 (Giorgi and Michetti 2021) represents an
13 opportunity for scaling up climate finance but also poses underlying issues of integrity (Nicol et al.
14 2018a; Shishlov et al. 2018) and additionality (Schneeweiss 2019), as further discussed in Section
15 15.6.6, as well as needs to be considered in the context of overall indebtedness and debt sustainability
16 (Sections 15.6.1, 15.6.3).

17 Mitigation continues to represent the lion's share of global climate finance (between 90% and 95%
18 between 2017 and 2020), and in particular renewable energy, followed by energy efficiency and
19 transport (UNFCCC 2018a; Buchner et al. 2019) (*high confidence*). While capacity additions on the
20 ground kept rising, falling technology costs in certain sectors (e.g. solar energy) has had a negative
21 impact on the year-on-year trend that can be observed in terms of volumes of climate finance (IRENA
22 2019a; BNEF 2019). However, such cost reduction could free up investment and financing capacities
23 for potential use in other climate-related activities.

24 Tracking adaptation finance continues to pose significant challenges in terms of data and methods.
25 Notably, the mainstreaming of resilience into investments and business decisions makes it difficult to
26 identify relevant activities within financial datasets (Agrawala et al. 2011; Averchenkova et al. 2016)
27 (Brown et al. 2015). Despite these limitations, evidence shows that finance for adaptation remains
28 fragmented and significantly below rapidly rising needs (Section 15.4 and WG2, TSU please confirm).
29 Further, there is increasing awareness about the need to better understand and address the interlinkages
30 between climate change adaptation and disaster-risk-reduction (DRR) towards achieving resilience
31 (OECD 2020a). (Watson et al. 2015) however, notes that between 2003 and 2014 of the 2 billion USD
32 that flowed through dedicated climate change adaptation funds, only 369 million USD explicitly went
33 to DRR activities (Climate Funds Update 2014; Nakhouda et al. 2014a,b; Watson et al. 2015). For the
34 private sector, insurance and reinsurance remain the dominant way to transfer risk, as discussed in
35 Section 15.6.4).

36 More generally, significant gaps remain to track climate finance comprehensively at a global level:

- 37 • Available estimates are based on a good coverage of investments in renewable energy and, where
38 available, energy efficiency and transport, while other sectors remain more difficult to track, such
39 as industry, agriculture and land use (UNFCCC 2018a; Buchner et al. 2019). (*high confidence*)
- 40 • In contrast to international public climate finance, domestic public finance data remain partial
41 despite initiatives to track domestic climate finance (e.g. (Hainaut and Cochran 2018)) and public
42 expenditures (for instance based on the UNDP's Climate Public Expenditure and Institutional
43 Review approach). (*high confidence*)

44 Data on private and commercial finance remains very patchy, particularly for corporate financing
45 (including debt financing provided by commercial banks), for which it is difficult to establish a link
46 with activities and projects on the ground. (*high confidence*). Further, as individual source of aggregate
47 reporting (UNFCCC 2018a; Buchner et al. 2019; FS-UNEP Centre and BNEF 2020) tend to rely on the

1 same main data sources (notably the BNEF commercial database for renewable energy investments) as
2 well as to cross-check numbers against similar other sources, there is a potential for ‘group-think’ and
3 bias.

4 Such data gaps as well as varying definitions of what qualifies as “climate” (or more broadly as “green”
5 and “sustainable”) not only pose a measurement challenge. They also result in a lack of clarity for
6 investors and financiers seeking climate-related opportunities. Such uncertainty can lead both to
7 reduced climate finance as well as to a lack of transparency in climate-related reporting (further
8 discussed in Section 15.6.1), which in turn further hinders reliable measurement.

9 In terms of finance provided and mobilised by developed countries for climate action in developing
10 countries, while accounting scope and methodologies continue to be debated (see Box 15.4), progress
11 has been achieved on these matters in the context of the UNFCCC (UNFCCC 2019b). A consensus,
12 however, exists, on a need to further scale up public finance and improve its effectiveness in mobilising
13 private finance (OECD 2020b), as well as to further prioritise adaptation financing, in particular towards
14 the most vulnerable countries (Carty et al. 2020). The relatively low share of adaptation in international
15 climate finance to date may in part due to a low level of obligation and precision in global adaptation
16 rules and commitments (Hall and Persson 2018). Further, providers of international climate finance
17 may have more incentive to support mitigation over adaptation as mitigation benefits are global while
18 the benefits of adaptation are local or regional (Abadie et al. 2013).

19 **‘START BOX 15.4 HERE’**

20 **Box 15.4 Measuring progress towards the 100 billion USD yr⁻¹ by 2020 goal - issues of method**

21 In 2009, at COP15, Parties to the UNFCCC agreed the following: “In the context of meaningful
22 mitigation actions and transparency on implementation, developed countries commit to a goal of
23 mobilizing jointly 100 billion USD dollars a year by 2020 to address the needs of developing countries.
24 This goal is further embedded as a target under SDG 13 Climate Action. Such finance may come from
25 a wide variety of sources, public and private, bilateral and multilateral, including alternative sources of
26 finance.” (UNFCCC 2009). While the parameters for what and how to count were not defined when the
27 goal was set, progress in this area has been achieved under the UNFCCC (UNFCCC 2019b) and via a
28 UN-driven independent expert review (Bhattacharya et al. 2020).

29 There remains well documented interpretations and debates on how to account for progress (Clapp et
30 al. 2012; Stadelmann et al. 2013; Jachnik et al. 2015; Weikmans and Roberts 2019). Different
31 interpretations relate mainly to the type and proportion of activities that may qualify as “climate” on
32 the one hand, and to how to account for different types of finance (and financial instruments) on the
33 other hand. As an example, there are different points at which financing can be measured, e.g. pledges,
34 commitments, disbursements. There can be significant lags between these different points in time, e.g.
35 disbursements may spread over time. Further, the choice of point of measurement can have an impact
36 on both the volumes and on the characteristics (geographical origin, labelling as public or private) of
37 the finance tracked. The enhanced transparency framework under the Paris Agreement may lead to
38 improvements and more consensus in the way climate finance is accounted for and reported under the
39 UNFCCC. Available analyses specifically aimed at assessing progress towards the 100 billion USD
40 goal remain rare, e.g. the UNFCCC SCF Biennial Assessments do not directly address this point
41 (UNFCCC 2018a). Dedicated OECD reports provide figures based on accounting for gross flows of
42 climate finance based on analysing activity-level data recorded by the UNFCCC (bilateral public
43 climate finance) and the OECD (multilateral public climate finance, mobilised private climate finance
44 and climate-related export credits) (OECD 2015a, 2019a, 2020b). For 2018, the OECD analysis resulted
45 in a total of 78.9 billion USD, out of which 62.2 billion USD of public finance, 2.1 billion USD of
46 export credits and 14.5 billion USD of private finance mobilised. Mitigation represented 73% of the
47 total, adaptation 19% and cross-cutting activities 8%.

1 Reports by Oxfam provide a complementary view on public climate finance, building on OECD figures
2 and underlying data sources to translate gross flows of bilateral and multilateral public climate finance
3 in grant equivalent terms, while also, for some activities, applying discounts to the proportion
4 considered as climate finance (Carty et al. 2016; Carty and Le Comte 2018 and Carty et al 2020). The
5 resulting annual averages for 2015– 2016 and 2017–2018 range between 32% (low bound) and 44%
6 (high bound) of gross public climate finance. The difference with OECD figures stems from the high
7 share represented by loans, both concessional and non-concessional, in public climate finance, i.e. 74%
8 in 2018 2018 (OECD 2020b).

9 A point of method that attracts much attention relates to how to account for private finance mobilised.
10 The OECD, through its Development Assistance Committee, established an international standard to
11 measure private finance mobilised by official development finance, which consists in methods tailored
12 to different financial mechanisms. These methods taking into account the role of, risk taken, and/or
13 amount provided by all official actors involved in a given project, including recipient country
14 institutions, thereby also avoiding risks of double counting. (OECD 2019b). MDBs apply a different
15 method (World Bank 2018a) in their joint climate finance reporting (AfDB et al. 2020)., which neither
16 correspond to the geographical scope of the 100 billion USD goal, nor address the issue of attribution
17 to the extent required in that context.

18 Notwithstanding methodological discussions under the UNFCCC, there is still some distance from the
19 100 billion USD a year commitment being achieved, including in terms of further prioritising
20 adaptation. While the scope of the commitment corresponds to only a fraction of the larger sums needed
21 (Section 15.4), its fulfilment can both contribute to climate action in developing countries as well as to
22 trust building in international climate negotiations. Combined with further clarity on geographical and
23 sectoral gaps, this can, in turn, facilitate the implementation of better-coordinated and cooperative
24 arrangements for mobilising funds (Peake and Ekins 2017).

25 **‘END BOX 15.4 HERE’**

26

27 **15.3.3 Fossil fuel-related and transition finance**

28 As called for by Article 2.1c of the Paris Agreement and introduced in Section 15.3.1, achieving the
29 goal of the Paris Agreement of holding the increase in the global average temperature to well below
30 2°C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5°C above
31 pre-industrial levels requires making all finance consistent with this goal. Data on investments and
32 financing to high GHG activities remain very partial and difficult to access, as relevant actors currently
33 have little incentive or obligations to disclose such information compared to reporting on and
34 communicating about their activities contributing to climate action. Further, the development of
35 methodologies to assess finance for activities misaligned with climate mitigation goals, for hard- and
36 costly-to-abate sectors such as heavy industries, as well as for activities that eventually need to be
37 phased out but can play a transition role for given period, remain work in progress. This results in
38 limited empirical evidence to date.

39 Scenarios compatible with a 1.5°C warming, however, make it clear that the share of fossil fuels in
40 energy supply has to decrease. For instance, the International Energy Agency (IEA) Net Zero by 2050
41 scenario relies on halting sales of new internal combustion engine passenger cars by 2035, rapid and
42 steady decrease of the production of coal (minus 90%), oil (minus 75%) and natural gas (minus 55%)
43 by 2050, and phasing out all unabated coal and oil power plants by 2040 (IEA 2021b). To avoid locking
44 GHG emissions incompatible with remaining carbon budgets, this implies a rapid scaling down of new
45 fossil fuel-related investments, combined with a scaling up of financing to allow energy and
46 infrastructure systems to transition (*high confidence*).

1 The IEA provides comprehensive analyses of global energy investments, estimated at about 1.8 trillion
2 USD a year over 2017–2019 (IEA 2019a, 2020a), and expected to reach that level again in 2021 after a
3 drop to about 1.6 trillion in 2020 (IEA 2021c). Energy investments represent about 8% of global GFCF
4 (Section 15.3.2.1). In the power sector, fossil fuel-related investments reached an estimated 120 billion
5 USD yr⁻¹ on average over 2019–2020, which remains well above the level that underpin the IEA’s own
6 Paris-compatible Sustainable Development Scenario (SDS) and Net Zero scenarios. The IEA observes
7 a similar inconsistency with for supply side new investments: in 2019–2020 on average yr⁻¹, an
8 estimated 650 billion USD were invested in oil supply and close to 100 billion USD in coal supply.
9 These estimates also result in fossil fuel investments remaining larger in aggregate than the total tracked
10 climate finance worldwide (Section 15.3.2.2). For oil and gas companies, which are amongst the world
11 largest corporations and sometimes government owned or backed, low-carbon solutions are estimated
12 to represent less than 1% of capital expenditure (IEA 2020b). As discussed in the remainder of this
13 Chapter, shifting investments towards low-GHG solutions requires a combination of conducive public
14 policies, attractive investment opportunities, as well as the availability of financing to finance such a
15 transition.

16 In terms of financing provided to fossil fuel investments, available analyses point out to a still significant
17 role played by commercial banks and export credit agencies. Commercial banks provide both direct
18 lending as well as underwriting services, the latter facilitating capital raising from investors in the form
19 of bond or share issuance. Available estimates indicate that lending and underwriting extended over
20 2016 –2019 by 35 of the world’s largest banks to 2,100 companies active across the fossil fuel life
21 cycle, reached USD 687 billion yr⁻¹ on average (Rainforest Action Network et al. 2020). Official export
22 credit agencies, which are owned or backed by their government, de-risk exports by providing
23 guarantees and insurances or, less often, loans. In 2016–2018, available estimates indicate the provision
24 of about 31 billion USD yr⁻¹ worth of fossil fuel-related official export credits, out of which close to
25 80% for the oil and gas, and over 20% for coal (DeAngelis and Tucker 2020).

26 Finance for new fossil fuel-related assets lock in future GHG emissions that may be inconsistent with
27 remaining carbon budgets and, as discussed above, with emission pathways to reach the Paris
28 Agreement goals. This inconsistency exposes investors and asset owners to the risk of stranded assets,
29 which results from potential sharp strengthening climate public policies, i.e. transition risk. As a result,
30 a growing number of investors and financiers are assessing climate-related risks with the aim to disclose
31 information about their current level of exposure (to both transition and physical climate-related risks),
32 as well as to inform their future decisions (TCFD 2017). Reporting to date is, however, inconsistent
33 across geographies and jurisdictions (CDSB and CDP 2018; Perera et al. 2019), with also a wide variety
34 of metrics, methodologies, and approaches developed by commercial providers that contribute to
35 disparate outcomes (Kotsantonis and Serafeim 2019; Boffo and Patalano 2020). Further, as developed
36 in Sections 15.6.1, there is currently not enough evidence in order to conclude whether climate-related
37 risk assessments result in increased climate action and alignment with the goals of the Paris
38 Agreement (e.g. 2° Investing Initiative (The 2° Investing Initiative and Wuest Partner 2020)).

39 As developed in Section 15.6.3, the insufficient level of ambition and coherence of public policies at
40 national and international level remains the root cause of the still significant misalignment of investment
41 and financing compared to pathways compatible with the Paris Agreement temperature goal (UNEP
42 2018). Such lack of coherence includes low pricing of carbon and of environmental externalities more
43 generally, as well as misaligned policies in non-climate policy areas such as fiscal, trade, industrial and
44 investment policy, and financial regulation (OECD 2015b), as further specified in the sectoral Chapters
45 6 to 12.

46 The most documented policy misalignment relates to the remaining very large scale of public direct and
47 indirect financial support for fossil fuel-related production and consumption in many parts of the world
48 (Bast et al. 2015; Coady et al. 2017; Climate Transparency 2020). Fossil fuel subsidies are embedded

1 across economic sectors as well as policy areas, e.g. from a trade policy perspective, in most countries,
2 import tariffs and non-tariff barriers are substantially lower on relatively more CO₂ intensive industries
3 (Shapiro 2020). Available inventories of fossil fuel subsidies (in the form of direct budgetary transfers,
4 revenue forgone, risk transfers, or induced transfers), covering 76 economies, indicate a rise to USD
5 340 billion in 2017, a 5% increase compared to 2016. Such trend is due to slowed down progress in
6 reducing support among OECD and G20 economies in 2017 (OECD 2018b) and to a rise in fossil-fuel
7 subsidies for consumption in several developing economies (Matsumura and Adam 2019), which, in
8 turn, reduces the efficiency of public instruments and incentives aimed at redirecting investments and
9 financing towards low-GHG activities.

10 As a result, the demand for fossil fuels, especially in the energy production, transport and buildings
11 sectors, remain high, and the risk-return profile of fossil fuel-related investments it still positive in many
12 instance (Hanif et al. 2019). Political economy constraints of fossil fuel subsidy reform continue to be
13 a major hurdle for climate action (Schwanitz et al. 2014; Röttgers and Anderson 2018), as further
14 discussed in Section 15.5.2. and Chapter 13.

15

16 **15.4 Financing needs**

17 **15.4.1 Definitions of financing needs**

18 Financing needs are discussed in various contexts, only one being international climate politics and
19 finance. Also, financing needs are used as an indicator for required system changes (when compared to
20 current flows and asset bases) and an indicator for near- to long-term investment opportunities from the
21 perspective of investors and corporates. Investment needs are widely used as an indicator focusing on
22 initial investments required to realise new infrastructure. It compares relatively well with private sector
23 flows dominated by return-generating investments but lacks comparability and explanatory power
24 regarding the needs in the context of international climate cooperation where considerations on
25 economic costs play a more substantial role. Chapter 12 elaborates on global economic cost estimates
26 for various technologies. This indicator includes both costs and benefits of options, of which
27 investment-related costs make up only one component. . Both analyses offer complementary insights.
28 There are financing needs not directly related to the realisation of physical infrastructure and which are
29 not covered in both, investment and cost estimates. For instance, the need for building institutional
30 capacity facilitating to achieve social and economic goals underpinning knowledge, skills, notional and
31 international cooperation might not be significant, but an enabling environment for future investments
32 would not be established without satisfying it. Moreover, comprehending financial needs for addressing
33 economic losses due to climate change can hardly be measured in terms of the indicators introduced
34 before.

35 Understanding the magnitude of the challenge to scale-up finance in sectors and regions requires a more
36 comprehensive (and qualitative) assessment of the needs. For finance to become an enabler of the
37 transition, domestic and international public interventions can be needed to ensure enough supply of
38 finance across sectors, regions and stakeholders. The location of financing needs and vicinity to capital
39 matter given home bias (Fuchs et al. 2017; OECD 2017a; Ito and McCauley 2019) (prioritizing own
40 country or regions), transaction costs and risk considerations (see also 15.2). Most of the finance is
41 mobilised domestically but the depth of capital markets is substantially greater in developed countries,
42 increasing the challenges to mobilise substantial volumes of additional funding for many developing
43 countries. The same applies to various stakeholders with limited connections into the financial sector.
44 In addition, governments' enabling financial market frameworks, guidelines and supportive
45 infrastructure is crucial for inclusive finance for the bottom of the pyramid (BoP), especially
46 disadvantaged and economically marginalised segments of society.

1 The attractiveness of a sector and region for capital markets depend on several factors. Some essential
2 elements are the duration of loan and profile as long term loans and heavily heterogeneous returns
3 represent challenges in financing mitigation technologies and policies. After the financial crisis and
4 restricted access to long-term debt, capital intensity of technologies and resulting long payback periods
5 of investment opportunities for mitigation technologies have been a crucial challenge (Bertoldi et al.
6 2021). Also, implicit discount rates applied during the investment decision process vary depending on
7 the payback profile, with research mainly covering the difference between the financing of assets
8 generating revenues versus costs (Jaffe et al. 2004; Schleich et al. 2016). In addition, a low correlation
9 between the climate projects and dominating asset classes might provide an opportunity in climate
10 action by satisfying the appetite of institutional investors, which tend to manage portfolios with
11 consideration of the Markowitz modern portfolio theory (optimizing return and risk of a portfolio
12 through diversification) (Marinoni et al. 2011). Transaction cost is a significant barrier to the diffusion
13 and commercialization of low-carbon technologies and business models and adaptation action. High
14 transaction costs, attributed to various factors, such as complexity and limited standardisation of
15 investments, limited pipelines, complex institutional and administrative procedures, create significant
16 opportunity costs of green investments comparing with other standard investments (IRENA 2016;
17 Nelson et al. 2016; Feldman et al. 2018). For example, transaction costs are commonly observed in
18 small-scale, dispersed independent renewable energy systems, especially in rural areas, and energy
19 efficiency projects (Hunecke et al. 2019). A more robust standardisation and alignment of Power
20 Purchase Agreement (PPA) terms with best practices globally has led to a substantially increased
21 interest in capital markets in developing countries (WBCSD 2016; Schmidt et al. 2019; World Bank
22 2021). Notably, Power Purchase Agreement (PPA) significantly increases the probability of more
23 balanced investment and development outcomes and ultimately more sustainable independent power
24 projects in developing countries. Therefore, lowering transaction costs would be essential for creating
25 investor appetite. The role of intermediaries bundling demand for financing has been demonstrated to
26 reduce transaction costs and to reach investors' critical size. In addition, new innovative approaches,
27 such as fintech and blockchain (see Section 15.6.8), have been discussed for providing new
28 opportunities in the energy sector.

29 Economic viability of investments – ideally not relying on the pricing of positive externalities – has
30 been a critical driver of momentum in the past. The falling technology costs and the competitiveness of
31 renewable technologies, especially solar PV and wind, have accelerated the deployment of renewable
32 technologies over the past years. renewable energy technologies now often competitive, even become
33 the cheapest, in many countries, even without financial support, (FS-UNEP Centre and BNEF 2015,
34 2016, 2017, 2018, 2019; IEA 2020c; IRENA 2020a) and without pricing of the avoided carbon
35 emissions. In contrast, the dependency on regulatory interventions and public financial support to create
36 financial viability has provided a source of volatile investor appetite. The annual volume of renewable
37 investment by country is often volatile reflecting ending and new regulations and policies (IEA 2019a).

38 For example, the recent Chinese policy direction towards tougher access to and a substantial cut in FiT
39 in 2018 led to a significant drop in renewable investment and new capacity addition in China (FS-UNEP
40 Centre and BNEF 2019; Hove 2020). However, the significant bouncing back of newly installed
41 capacity (72 GW wind power and 47 GW solar power in 2020) shows the strong development of zero
42 carbon power generation driven by lower cost and policies to support them by energy revolution
43 strategies in China. Investors had proven to be willing to work with transparent support mechanisms,
44 such as with the Clean Development Mechanism (CDM), which stimulated emission reductions and
45 allowed industrialised countries to implement emission-reduction projects in developing countries to
46 meet their emission targets (Michaelowa et al. 2019). However, the collapse of carbon markets and
47 prices, especially of the EU ETS, led to the continuous decline of Certified Emission Reductions (CER)
48 issuances from CDM in the past years (World Bank Group 2020). Also, the dependency on regulatory
49 intervention to ensure fair market access only has proven to burden investor appetite.

1 A significant share of investment needs in heavily regulated sectors, such as electricity, public transport,
2 and telecom, emphasises the importance of regulatory intervention, such as ownership and market
3 access (OECD 2017b). For instance, energy-system developments require effective and credible
4 commitments and action by policy-maker to ensure an efficient capital allocation aligned with climate
5 targets (Bertram et al. 2021).

6 There are a lot of discussion about the regulated ownership of the private sector (European Commission
7 2017) and the restructuring of electricity market contributed to low level of investment in baseline
8 electricity capacity and in investment research and innovation. This changes create uncertainty of
9 investment, and barriers to market entry and exit also potentially limit the competition in the market
10 and restrict the entrance of new investment (Finon 2006; Joskow 2007; Grubb and Newbery 2018). This
11 is also the case in developing countries (Foster and Rana 2020).

12 The positive development in the energy sector has benefitted from the evident stand-alone character of
13 renewable energy generation projects. First movers realised these projects with investors and developers
14 acting from conviction (Steffen et al. 2018). Such action is not possible to this extent in energy
15 efficiency with related investment rather representing an add-on component and consequently requiring
16 the support of decision-makers used to business-as-usual projects. Despite the benefits that
17 improvement of energy efficiency has in contributing to curbing energy consumption, mitigating
18 greenhouse gas emissions, and providing multiple co-benefits (IEA 2014a), investment in energy
19 efficiency is at a low priority for firms, and the financial environment is not favourable due to lacking
20 awareness of energy efficiency by financial institutions, existing administrative barriers, lack of
21 expertise to develop projects, asymmetric information, and split incentives (UNEP DTU 2017; Cattaneo
22 2019). While Energy Service Companies (ESCO) business models are expected to facilitate the
23 investment in energy efficiency by sharing a portion of financial risk and providing expertise, there has
24 been limited progress made with ESCO business models, and only slightly over 20% of projects used
25 financing through ESCOs (UNEP DTU 2017).

26 The investment needs and existing challenges differ by sector. Each sector has different characteristics
27 along the arguments listed above making the supply of finance by commercial investors an enabling
28 factor or barrier. In the transport sector, transformation towards green mobility would provide
29 significant co-benefits for human health by reducing transport-related air pollution, so the transport
30 sector cannot achieve such transformation in isolation with other sectors. However, a considerable
31 involvement of the public sector in many transportation infrastructure projects is given, and the absence
32 of a standard solution increases transaction costs (including bidding package, estimating, drawing up a
33 contract, administering the contract, corruption, and so on). Financial constraints, including access to
34 adequate finance, pose a significant challenge in the agriculture sector, especially for SMEs and
35 smallholder farmers. The distortion created by government failure and a lack of effective policies create
36 barriers to financing for agriculture. The inability to manage the impact of the agriculture-related risks,
37 such as seasonality, increases uncertainty in financial management. Moreover, inadequate
38 infrastructure, such as electricity and telecommunication, makes it difficult for financial institutions to
39 reach agricultural SMEs and farmers and increases transaction costs (World Bank 2016). Low
40 economies of scale, low bargaining power, poor connectivity to markets, and information asymmetry
41 also lead to higher transaction cost (Pingali et al. 2019). In the industrial manufacturing and residential
42 sector, gaining energy efficiency remains one of the critical challenges. Investment in achieving energy
43 efficiency encounters some challenges when it may not necessarily generate direct or indirect benefits,
44 such as increase in production capacity or productivity and improvement in product quality. Also, early-
45 stage, high upfront cost and future, stable revenue stream structure suggest the needs for a better
46 enabling environment, such as a robust financial market, awareness of financial institutions, and
47 regulatory frameworks (e.g., stringent building codes, incentives for ESCOs) (IEA 2014a; Barnsley et
48 al. 2015).

1

2 15.4.2 Quantitative assessment of financing needs

3 Multiple stakeholders prepare and present quantitative financing needs assessments with methodologies
4 applied to vary significantly representing a major challenge for aggregation of needs (i.e. (Osama et al.
5 2021) for African countries), most of them with a focus on scenarios likely to limit warming to 2°C or
6 lower. The differences relate to the scope of the assessments regarding sectors, regions and periods,
7 top-down versus bottom-up approaches, and methodological issues around boundaries of climate-
8 related investment needs, particularly full vs incremental costs and the exclusion or inclusion of
9 consumer-level investments. Information on investment needs and financing options in NDCs mirror
10 this challenge and is heavily heterogeneous (Zhang and Pan 2016).

11 In particular, for global approaches, modelling assumptions are often heavily standardised, focusing on
12 technology costs. Only limited global analysis is available on incremental costs and investments,
13 reflecting the reality of developing countries, also considering the interplay with significant
14 infrastructure finance gaps, and can hardly serve as a robust basis for negotiations about international
15 public climate finance. The focus on investment irrespective of uncertainty as well as other qualitative
16 aspects of needs does not allow for a straightforward analysis of the need for public finance to leverage
17 private sector financing and of the country heterogeneity in terms of investment risks and access to
18 capital (Clark et al. 2018).

19 One source of uncertainty about the investment estimates for the power sector is the evolution of the
20 levelized cost of technical options in the future for example the continuation of the observed declining
21 trend of renewable energy (IRENA 2020b) which has been underestimated in many modelling
22 exercises. The learning by doing processes and economies of scale might be at least partially
23 outweighed, in all countries and more specifically in SIDS and other developing countries because of
24 different risk factors, scales of installations, accessibility, and others (Lucas et al. 2015; van der Zwaan
25 et al. 2018). These parameters, together with transaction costs/soft costs (see Section 15.5), financing
26 costs and the level of technical competences need to be better represented in the future to represent the
27 “climate investment trap” in many developing countries (IDB 2019). This “climate investment trap”, as
28 flagged by (Ameli et al. 2021b) is created by existing and expected physical effects of climate change,
29 higher financing costs and resulting lower investment levels in developing countries. Applying
30 significantly standardised assumptions can consequently not provide robust insights for specific country
31 groups. This will require progress in the spatiotemporal granularity of the models (Collins et al. 2016).

32 Another source of uncertainty about the financing needs is the interplays between a) the baseline
33 economic growth rates, b) the link between economic growth and energy demand, including rebound
34 effects of energy efficiency gains c) the evolution of microeconomic parameters such as fossil fuel
35 prices, interest rates, currency exchange rates d) the level of integration between climate policies and
36 sectoral policies and their efficacy and e) the impact of climate policies on growth and the capacity of
37 fiscal and financial policies to offset their adverse effect (see (IPCC 2018) and AR5 (IPCC 2014, 2018)).
38 Integrated assessment models (IAMs) try to capture some to these interplays even though they typically
39 do not capture the financial constraints and the structural causes of the infrastructure investment gap.
40 Many of them rely on growth models with full exploitation of the means of production (labour and
41 capital). They nevertheless provide useful indications of the orders of magnitude at play over the long
42 run, and the determinants of their uncertainty. Global yearly average low-carbon investment needs until
43 2030 for electricity, transportation, AFOLU and energy efficiency measures incl. industry and buildings
44 are estimated between 3% and 6% of the world’s GDP according to the analysis in section 15.5. The
45 incremental costs of low carbon options are less than that and their funding could be achieved without
46 reducing global consumption by reallocating 1.4% to 3.9% of global savings, 2.4% on average (see Box
47 4.8 of (IPCC 2018)) currently flow towards real estate, land and liquid financial vehicles. For the short

1 term decisions, the major information they give is the uncertainty range because this is an indicator of
2 the risks decision-makers need.

3 While the IAMs database provides good transparency with regard to technology costs for electricity
4 generation, assumptions driving in particular investments in energy efficiency are rarely made available
5 in both, IAM based assessments but also other studies. Taking into account the much broader range of
6 tested and untested technologies the confidence levels, in particular for 2050 estimates, remains low but
7 can provide an initial indication. Also, the ranges allow for a rough indication on possible “green”
8 investment volumes and respective asset allocation for financial sector stakeholders.

9 **Using global scenarios assessed in Chapter 3 for assessing investment requirements**

10 Tables 15.2 and 15.3 present the analysis of investment requirements in global mitigation pathways
11 assessed in Chapter 3 for key energy sub-sectors for scenarios likely to limit warming to 2°C or lower.
12 These pathways explore the energy, land-use, and climate system interactions and thus help identify
13 required energy sector transformations to reach specific long-term climate targets. However, reporting
14 of investment needs outside the energy sector was scarce, reducing the explanatory power of total in
15 the context of overall investment needs (Bertram et al. 2021)(Ekholm et al. 2013; McCollum et al.
16 2018); and Box 4.8 in (IPCC 2018)). The modelling of these scenarios is done with a variation of
17 scenario assumptions along different dimensions (inter alia policy, socio-economic development and
18 technology availability), as well as with different modelling tools which represent different assumptions
19 about the structural functioning of the energy-economy-land-use system (see “Annex III: Scenarios and
20 modelling methods” for details). Tables 15.2 and 15.3 focus on the near-term (2023–2032) investment
21 requirements in the energy sector and how this differs depending on temperature category (Figure 3.36
22 and 3.37 in Chapter 3) presents the data for the medium-term (2023-2052)). The results highlight both
23 requirements for increased investments and a shift from fossil towards renewable technologies and
24 efficiency for more ambitious temperature categories. The substantial ranges within each category
25 reflect multiple pathways, differentiated by socio-economic assumptions, technology etc. It is necessary
26 to open up these extra dimensions and contrast them with national and sub-regional analysis to
27 understand how investment requirements depend on particular circumstances and assumptions within a
28 country for a specific technology. Limiting peak temperature to levels of 1.5°C–2°C requires rapid
29 decarbonization of the global energy systems, with the fastest relative emission reductions occurring in
30 the power generation sector (Hirth and Steckel 2016; Luderer et al. 2018).

31

32 **Table 15.2 Global average yearly investments from 2023–2032 for Electricity supply in billion**
33 **USD₂₀₁₅.**

Category	Fossil	Nuclear	Storage	T&D	Non-Biomass Renewables	Thereof Solar	Thereof Wind
C1	53 [50]	127 [52]	221 [39]	549 [50]	1190 [52]	498 [52]	390 [52]
(Range)	(34;115)	(85;165)	(88;295)	(422;787)	(688;1430)	(292;603)	(273;578)
C2	78 [100]	116 [92]	57 [66]	489 [81]	736 [96]	312 [96]	237 [96]
(Range)	(50;129)	(61;150)	(37;139)	(401;620)	(482;848)	(181;385)	(174;328)
C3	75 [221]	96 [190]	28 [129]	389 [157]	639 [207]	220 [207]	266 [207]
(Range)	(52;129)	(50;122)	(8;155)	(326;760)	(432;820)	(167;345)	(137;353)

Note: Global average yearly investments from 2023-2032 in USD₂₀₁₅). Electricity subcomponents are not exhaustive, hydro, geothermal, biomass and others are not shown, as these are shown to be of smaller magnitude (Chapter 3). Difference between non-biomass renewables and solar/wind represents hydro and in some scenarios geothermal, tidal, and ocean. Scenarios are grouped into common AR6 categories (vertical axis, C1-C3). The numbers represent medians across all scenarios within one category, and rounded brackets indicate inter-quartile ranges, while the numbers in squared brackets indicate number of scenarios. C6, C7, and C8 not shown in Table 15.2. Reference C5 category for T&D is 364bn (294bn to 445bn) [111] used for calculation of incremental needs in Figure 4.

34

1 This requires fast shifts of investment as infrastructures in the power sector generally have long lifetimes
 2 of few decades. In the scenarios limiting warming to below 1.5°C, investments into non-biomass
 3 renewables (especially solar and wind, but also including hydro, geothermal, and others not shown in
 4 Table 15.2) increase to over 1 trillion USD yr⁻¹ in 2030, increasing by more than factor 3 over the values
 5 of around 250–300 billion USD yr⁻¹ that has been relatively stable over the last decade (IEA 2019a).
 6 Overall, electricity generation investments increase considerably, reflecting the higher relevance of
 7 capital expenditures in decarbonised electricity systems. While decreasing technology costs have
 8 substantially reduced the challenge of high capital intensity, still remaining relative disadvantages in
 9 terms of capital intensity of low-carbon power technologies can especially create obstacles for fast
 10 decarbonization in countries with high interest rates, which decrease the competitiveness of those
 11 technologies (Iyer et al. 2015; Hirth and Steckel 2016; Steckel and Jakob 2018; Schmidt et al. 2019).
 12 CCS as well as nuclear will not drive investment needs until 2030, given considerably longer lead-times
 13 for these technologies, and the lack of a significant project pipeline currently.

14

Note: Average yearly investments from 2023-2032 for Electricity generation capacity, by aggregate regions (in billion USD₂₀₁₅). Further notes see Table 15.2. Reference C5 category for T&D shown in Table 2 as it is used for calculation of incremental needs for Figure 4. Vertical axis vertical axis, C4-C8 except T&D not shown. Reference C5 category for T&D shown because it is used for calculation of incremental needs for Figure 4.

1

2 What is apparent is that the bulk of investment requirements corresponds to medium- and low-income
3 countries such as Asia, Latin America and the Middle East and Africa, as these still have growing
4 energy demand and it is still considerably lower than the global average. This illustrates a vital
5 opportunity to ensure the build-up of sustainable energy infrastructures in these regions and constitutes
6 a risk of additional carbon lock-in if investments into fossil infrastructures, especially coal-fired power
7 plants and uncontrolled urban expansion, continue.

8 Investment needs in electrification derived from IAMs do not include systematically investments in
9 end-use equipment and distribution (See Box 4.8 in IPCC 1.5°C (IPCC 2018)). Model-based estimates
10 of investment needs don't have the regional granularity to single out LDCs, as model regions typically
11 are defined based on geographic proximity and therefore aggregate LDCs and other countries. With the
12 average electricity consumption per capita in Africa increasing to 0.68-0.87 (1.43-2.92) MWh in 2030
13 (2050) yr⁻¹ and remaining at the very low end of the global range [0.46 in Africa compared to the upper
14 end of 12.02 in North America, MWh per capita and year in 2020], the targeted full electrification until
15 2030 appears unrealistic across all scenarios. SEforAll and IEA estimate assume investment needs to
16 decentralised end-user electrification to come in around 40 billion USD on average until 2030
17 (SEforALL and CPI 2020; IEA 2021d).

18 **Quantitative analysis of investment needs in energy generation based on IRENA and IEA data** 19 **and comparison to AR6 scenario database output.**

20 According to IRENA, the government plans in place today call for investing at least 95 trillion USD in
21 energy systems over the coming three decades (2016–2050) (IRENA 2020c). Redirecting and
22 increasing investments to ensure a climate-safe future (Transforming Energy Scenario) would require
23 reaching on average around 1 USD trillion yr⁻¹ (average until 2030) for electricity generation as well as
24 grids and storage, increasing to above 2 USD trillion yr⁻¹ (average until 2030) in the 1.5 scenario
25 (IRENA 2021). IEA's respective SDS and NZE scenarios come in at average annual investments
26 between 1.1 USD trillion yr⁻¹ and 1.6 USD trillion yr⁻¹ (average until 2030) (IEA 2021b). These
27 additional data points for the C1 and C3 category underpin the range presented in the IAM database for
28 needs until 2032 despite the slightly varying periods.

29 In contrast to the IAMs, IRENA and IEA assessments do not allow for an analysis of mitigation-driven
30 investment needs in transmission and distribution which likely results in an overestimation of the
31 mitigation driven investment needs in their analysis.

32 It is worth highlighting that driven by technology cost assumptions IRENA forecasts falling average
33 annual investments needs for energy, but also energy efficiency, for the period 2030-2050 compared to
34 2020-2030. In the 1.5-S scenario the total annual investment needs excluding fossils and nuclear
35 decrease from 5.0 trillion USD until 2030 yr⁻¹ to 3.8 trillion USD yr⁻¹ for 2030-2050 (IRENA 2021). In
36 IAM scenarios of Category C1, Electricity supply investments (incl. generation, T&D, and storage)
37 remain flat at 2.2 trillion USD yr⁻¹ through the coming three decades in absolute terms. Given rising
38 GDP, the complementary methods and sources thus consistently point to a peak in electricity supply
39 investments as a percentage of GDP in mitigation scenarios in the coming decade. This reflects the fact
40 that the coming decade requires low-carbon power generation investments to both cover the demand
41 increase and (partly premature) replacement of fossil generation capacities, both concentrated in

1 emerging and developing countries. Relative investment numbers for electricity measured against GDP
2 then decrease towards 2050, as they only need to cover natural replacement and increasing demands
3 (which due to electrification will also pick up in developed countries), and due to further declining
4 technology costs. Investments for low-carbon fuel supply like hydrogen and synthetic fuels, and for
5 direct electrification equipment (heat pumps, electric vehicles, etc.) scale up from much lower levels
6 and will likely continue to grow as a share of GDP until mid-century, though uncertainties and
7 accounting is still much more uncertain. (Bertram et al. 2021).

8 **Quantitative analysis of investment needs in other sectors.** As described above investment needs in
9 non-energy sectors tend to be ignored in many integrated assessment models with studies for individual
10 countries or regions providing a more fragmented picture only. However, the quality of estimates is
11 likely not to be less robust given the drawbacks of integrated assessment models.

12 **Energy efficiency** Estimates on energy investment needs vary significantly with a low level of
13 transparency with regard to underlying technology cost assumptions burdening the confidence levels.

14 IRENA only selectively reports financing needs for EE in buildings and industry as separate categories.
15 For the 1.5-S average yr⁻¹ needs until 2050 come in at 963 billion USD for buildings, 102 billion USD
16 for heat pumps, and 354 billion USD for industry. Applying the relative share of these categories on
17 higher total needs until 2030, around 1.8 trillion USD yr⁻¹ in buildings and 1.7 trillion USD yr⁻¹ in
18 industry are needed in the 1.5-S and TES scenario. For the TES total EE investment needs until 2030
19 are stated at 29 trillion USD translating into an yearly average of around 1.8 trillion USD yr⁻¹. IEA
20 estimates come in at a much lower level at 0.6 and 0.8 billion USD yr⁻¹ on average between 2026-2030
21 for their SDS and NZE scenarios.

22 **Transportation** For the transportation sector, OECD has presented the most comprehensive assessment
23 of financing needs in the AR6 database based on IEA data with the annual average coming in at 2.7
24 trillion USD in the 2°C (66%) scenario between 2015 and 2035. The assessment comprises road, rail
25 and airports/ports infrastructure with only rail infrastructure being considered in our analysis amounting
26 to 0.4 trillion USD on average until 2030.

27 On a regional level, (Oxford Economics 2017) shows, that annual infrastructure investments between
28 2016 and 2040 vary widely. For all available countries (n=50) estimates counts close to 0.4 trillion
29 USD, including 0.2 trillion USD for China. Based on available data for 9 African countries, investments
30 in rail infrastructure range from 0.1 billion USD in Senegal to 1.6 billion USD in Nigeria. (Osama et al.
31 2021) highlights a 4.7 billion USD financing gap for African countries in the transport sector. In Latin
32 America the report identifies Brazil as frontrunner of required rail investments with 8.3 billion USD,
33 followed by Peru with 2.3 billion USD. Totally, developed countries mounting up to 117 billion USD
34 yr⁻¹ (n=14, mean=8.35bn USD) for rail infrastructure funding needs, succeeded by developing countries
35 (excl. LDCs) with 26 billion USD yr⁻¹ (n=28, mean=0.93bn USD, excluding China).

36 Fisch-Romito and Guivarch (2019) show, by endogenizing the impact of urban infrastructure policies
37 on mobility needs and modal choices that transportation investment needs globally might be lower in
38 low-carbon pathways compared with baselines, with lower investments in road and air infrastructure.
39 This does mean that higher investments are not needed over the following two decades; this means, this
40 is confirmed by (Rozenberg and Fay 2019) that strong policy integration between urban, transportation
41 and energy policies reduce the total investment gap..

42 IRENA as well as IEA have presented estimates for energy efficiency investments in the transport
43 sector. For the 1.5-S scenario, IRENA indicates average investment needs of 0.2 trillion USD yr⁻¹ for
44 electric vehicle infrastructure, 0.2 trillion USD yr⁻¹ for transport energy efficiency and 0.3 trillion USD
45 yr⁻¹ for EV batteries (IRENA 2020d) (average until 2030). IEA indicates a total of around 0.6 and 0.8
46 trillion USD yr⁻¹ for transport energy efficiency in the SDS and IEA scenario for the 2026-2030 period
47 (IEA 2021c). Many investment categories relating to mitigation options in particular with regard to

1 behavioural change and transport mode changes (see Chapter 10, Figure SPM.8) are neglected in these
2 analyses despite their significant mitigation potential.

3 **AFOLU** The Food and Land use Coalition estimates additional investment needs for ten critical
4 transitions for the global food and land use systems to achieve the LTGG and SDGs. Additional annual
5 investment needs until 2030 add up to 300-350 billion USD. Considering the change in global diets as
6 well as the land-based nature-based solutions only, annual investment needs would come in between
7 110–135 billion USD. Chapter 7 stresses the importance of opportunity costs for AFOLU mitigation
8 options, in particular for afforestation projects [cross-reference], and derives average yearly investment
9 needs of around 278 billion USD yr⁻¹ until 2030 and 431 USD billion yr⁻¹ in the next several decades,
10 including opportunity costs. The estimate is based on an assumption of emission reductions consistent
11 with pathways C1-C4, leading to average abatement of 9.1 GtCO₂ yr⁻¹ (median range 6.7 – 12.3 GtCO₂
12 yr⁻¹) from 2020-2050 and marginal costs of 100 USD per ton CO₂, excluding investments in BECCS
13 and changes in food consumption and food waste (see Section 7.4). The largest investments are
14 projected to occur in Latin America, Southeast Asia, and Africa, constituting 61% of total expenditure.
15 The implied change of land use might trigger negative effects on other SDGs which need to be addressed
16 to offer robust safeguards and labelling for investors.

17

18 However, given the strong interlinkage of the presented transitions and accumulated effects, climate
19 change related investments can hardly be separated (The Food and Land Use Coalition 2019).
20 (Shakhovskoy et al. 2019) present an overview of financing needs of small-scale farmers globally,
21 however, without focusing on the required climate related investments. According to their assessment
22 270 million smallholder farmers in South/South-East Asia, sub-Saharan Africa and Latin America face
23 approximately 240 billion USD of financing needs, thereof 100 billion USD short-term agricultural
24 needs, 88 billion USD long-term agricultural needs and 50 billion USD non-agricultural needs (
25 Shakhovskoy et al. 2019). These numbers can only provide “an indication of the magnitude of the
26 climate investments required in small-scale agriculture” (CPI 2020). The following table summarises
27 the studies used as well as adjustments made to determine needs for the gap discussion in Section 15.5.2.
28

29

Table 15.4 Sector studies to determine average financing needs.

Sector	Studies	Global ranges tr USD yr ⁻¹ - <i>Confidence Level</i>	Regional breakdown	Comment
Energy	IAM database, SEforAll (SEforALL and CPI 2020), IRENA 1.5-S and TES scenarios (IRENA 2021), IEA SDS and NZE scenarios (IEA 2021b)	0.7-1.6 <i>High confidence</i>	Detailed breakdown for R10 possible for IAM database and applied to the derived range	Wide ranges primarily driven by varying assumptions with regard to grid investments relating to the increased RE penetration.
Energy Efficiency	IRENA 1.5-S and TES scenarios, IEA SDS and NZE scenarios	0.6-1.8 <i>Medium confidence</i>	Adjustments required to regional categorization by IEA and IRENA	Medium confidence levels due to missing transparency with regard to underlying assumptions on technology costs. Low-to-medium confidence level

						on regional allocations due to required adjustments.
Transport	OECD/IEA (OECD 2017b) and Oxford Economics (Oxford Economics 2017) on rail investment data, IRENA 1.5-S and TES scenarios, IEA SDS and NZE scenarios for transport (energy efficiency) and electrification	1.0-1.2	<i>Medium confidence</i>	Adjustments required to regional categorization by IEA and IRENA	<i>Low-medium confidence</i>	Needs including battery costs, not total costs, of EVs, likely underestimation of needs due to missing data points on rail infrastructure.
AFOLU	Chapter 7 analysis, Section 7.4; The Food and Land use Coalition (Shakhovskoy et al. 2019)	0.1-0.3	<i>High confidence</i>	Breakdown for R10 possible for chapter 7 analysis	<i>Medium confidence</i>	Upper end of range incl. opportunity costs as these likely increase costs of investment of land.

1 Note: Total range 2,4 trillion to 4.8 trillion USD yr⁻¹.

2

3 **Adaptation financing needs.**

4 Financing needs for adaptation are even more difficult to define than those of mitigation because
 5 mobilizing specific adaptation investments is only part of the challenge since ultimately improving
 6 societies' adaptive capacities depends on the SDGs' fulfilment (Hallegatte et al. 2016). Bridging the
 7 investment gap on irrigation, water supply, healthcare, energy access, and quality buildings is an essential
 8 enabling condition for adapting to climate change. The scenario analysis conducted by (Rozenberg and
 9 Fay 2019) show that fulfilling the SDGs to improve the adaptive capacity of low and middle income
 10 countries would require investments in water supply, sanitation, irrigation and flood protection that
 11 would account for about 0.5% of developing countries GDP in a baseline scenario to 1,85% and 1% with
 12 a strong and anticipatory policy integration (USD 664 billion and 351 billion on average by 2030).

13 Most studies choose to assess public sector projects ignoring household level investments as well as
 14 private sector adaptation (UNEP 2018; Buchner et al. 2019). UNEP 2016 Adaptation Gap Report
 15 estimates adaptation financing needs amounting to 140–300 billion USD yr⁻¹ by 2030 and 280–500
 16 billion USD yr⁻¹ by 2050 (UNEP 2016, 2018, 2021). Over 100 countries included adaptation components
 17 in their intended NDCs (INDCs) and approximately 25% of these referenced national adaptation plans
 18 (NAPs) (GIZ 2017a) but estimates of the financing required for NAP processes is not available (NAP
 19 Global Network 2017). These NAPs, as formally agreed under the UNFCCC in 2010 are iterative,
 20 continuous processes that have multiple stages with a developmental phase that requires country specific
 21 financing of primarily packages domestic sources, grants, bond issuance or debt conversion (NDC
 22 Partnership 2020). At the same time, multilateral climate funds such as the Green Climate Fund and the
 23 GEF/LDCF offer 'readiness and preparatory support' and implementation for the NAPs and adaptation
 24 planning process (GCF 2020a; GEF 2021a,b). There has been no significant updating of adaptation cost
 25 estimates since (UNEP 2016, 2018). The Global Commission on Adaptation makes the case that
 26 investing USD 1.8 trillion in early warning system, climate resilient infrastructure, global mangrove and
 27 resilient water resources would generate about USD1.7 trillion in benefits due to avoided cost and non-
 28 monetary and social resources (Verkooijen 2019; UNEP 2021).

1 There is increasing recognition of rising adaptation challenges and associated costs within and across
2 Developed countries. Undoubtedly many developed countries are spending more on wide range of
3 adaptation issues both as preventive measures and building resilience (greening infrastructure, climate
4 proofing major projects and managing climate related risks) against the impacts of climate change
5 extreme weather events (USGCRP 2018). Developed countries climate change adaptation spending
6 covers areas such as federal insurance programmes, federal, state and local property and infrastructure,
7 supply chains, water systems.

8

9 **15.5 Considerations on financing gaps and drivers**

10 **15.5.1 Definitions**

11 The analysis of financing gaps in climate action, which is used to measure implementation action and
12 mitigation impact (FS-UNEP Centre and BNEF 2019) cannot be carried out as a pure demand-side
13 challenge, in isolation from the analysis of barriers to deploy funds (e.g. (Ramlee and Berma 2013))
14 and to take investment initiatives. These barriers are friction that prevents socially optimal investments
15 from being commercially attractive' (Druce et al. 2016). They are at the root of the "microeconomic
16 paradox" of a deficit of infrastructure investments despite a real return between 4% and 8%
17 (Bhattacharya et al., 2016), of the low share of carbon saving potentials tapped by dedicated policies
18 such as energy renovation programmes (Ürge-Vorsatz et al. 2018), and, more generally of a demand
19 for climate finance lower than the volume of economically viable projects (de Gouvello and Zelenko
20 2010; Timilsina et al. 2010)..

21 A few exercises tried and assess the consequences of the perpetuation of these drivers on the magnitude
22 of the financing gap. They suggest, comparing the evolution of the infrastructure investment trends
23 (beyond energy) by comparison with what they should be in an optimal scenario, a cumulative deficit
24 between 15.9% in 2035 (Oxford Economics 2017) and 32% (Arezki et al. 2016). The volume of this
25 gap is of the same order of magnitude than the incremental infrastructure investments (energy and
26 beyond) for meeting a 1.5°C target, 2.4 % of the world GDP on average, (Box 4.8, IPCC 1.5°C 2018
27 (IPCC 2018)) calculated by exercises assuming no pre-existing investment gap. This figure is consistent
28 with the 1.5% to 1.8% assessed by (European Commission 2020) for Europe and the 2% of the (IMF
29 2021d) for the G20 which do not encompass many developing countries of which economic take-off is
30 today fossil fuels dependent. For low and middle income economies, (Rozenberg and Fay 2019) results
31 suggest to increase the infrastructure investments by 2.5 to 6 percentage points of the GDP to cover
32 both the reduction of the structural investment gap and the specific additional costs for bridging it with
33 low carbon and climate resilient options. These assessments indicate the challenge at stake but do not
34 exist at very disaggregated sectoral and regional levels for sectors other than energy.

35 The below quantitative analysis does not differentiate between financing gaps driven by barriers within
36 or outside the financial sector given that the IAM models as well as most other studies used do not
37 incorporate actual risk ranges depending on policy strength and coherence and institutional capacity,
38 low-carbon-policy-risks, lack of long-term capital, cross-border currency fluctuation, and pre-
39 investment costs and barriers within the financial sector that are discourage private sector funding. They
40 comprise short-termism (e.g. (UNEP Inquiry 2016b)), high perceived risks for mitigation relevant
41 technologies and/or regions (information gap through incomplete/ asymmetric information, e.g. (Clark
42 et al. 2018)), lack of carbon pricing effects (e.g. (Best and Burke 2018)), home bias (results in limited
43 balancing for regional mismatches between current capital and needs distribution, e.g. (Boissinot et al.
44 2016)), and perceived high opportunity and transaction costs (results from limited visibility of future
45 pipelines and policy interventions; SME financing tickets and the missing middle, e.g. (Grubler et al.
46 2016)). In addition, barriers outside the financial sector will have to be addressed to close future

1 financing gaps. The mix and dominance of individual barriers might vary significantly across sectors
2 and regions and is analysed below

3 The interpretation of the quantitative analysis thus needs to be performed, taking into account the
4 qualitative needs assessment in Section 15.4.1 and the evolution of parameters that determine the risk-
5 weighted relative attractiveness low carbon and climate resilient investments compared to other
6 investment opportunities. With some institutions having announced climate finance commitments
7 and/or targets (see also Box 15.4 Measuring progress towards the 100 billion USD yr⁻¹ by 2020 goal:
8 issues of method), the actual asset allocation of commercial financial sector players including sectoral
9 and regional focus will respond to tangible and financially viable investment opportunities available in
10 the short-term. Robust long-term pathways to create such conditions for a significant private sector
11 involvement do rarely exist and expectations on private sector involvement in some critical
12 sectors/regions might be too high (Clark et al. 2018).

13

14 **15.5.2 Identified financing gaps for sector and regions**

15 The following section compares current climate finance flows as reported by CPI and IEA to needs
16 derived in section 15.4 ignoring the slight mismatch in time horizons. The analysis ignores interlinked
17 gaps in particular infrastructure investment gaps and other SDG-related investment gaps, which need
18 to be addressed in parallel to reach the LTGG but also at least partially to facilitate green investments.

19 Total investments in mitigation need to increase by around 3 and 6 times with significant gaps existing
20 across sectors and regions (*high confidence*). The findings on still significant gaps and limited progress
21 over the past few years to some extent seem to contradict the massive increase in commitments by
22 financial institutions. As discussed in section 15.6 the investment gap is not due to global scarcity of
23 funds.

24 However, these investment gaps have any little explanatory power in terms of the magnitude of the
25 challenge to mobilise funding. In addition to measurement challenges from different definitions and
26 data gap, sectors and regions offer highly divergent financial risk-return profiles and economic costs as
27 well as standardization, scalability and replicability of investment opportunities as basis for private
28 sector investment appetite. Moreover, soft costs and institutional capacity for enabling environment that
29 can be prerequisite for addressing financing gap are ignored when focusing on investment cost needs.

30

31

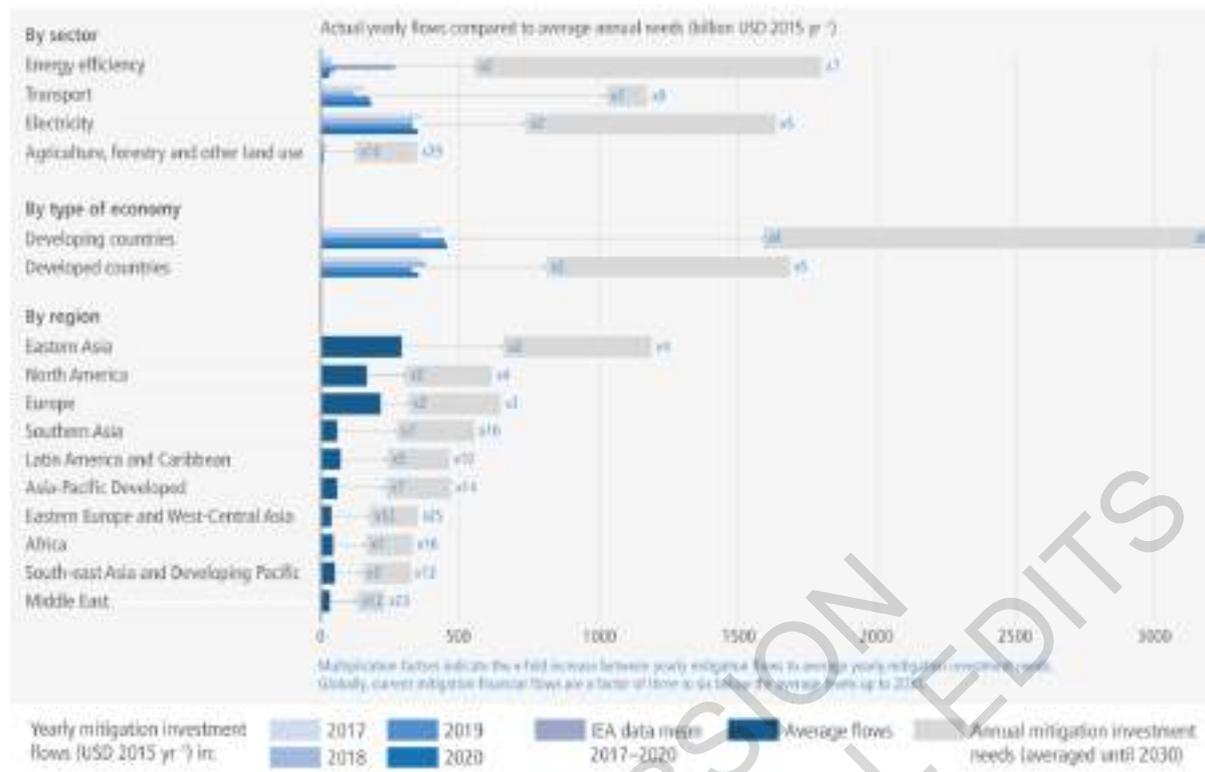

Figure 15.4 Breakdown of average investment flows and needs until 2030

Flows: Yearly CPI data for the *Agriculture and Forest, Electricity, Energy Efficiency, and Transport*.

Adaptation pegged transactions are excluded. Technical assistance (i.e. Policy and national budget support or capacity building) and other non-technology deployment financing excluded from analysis.

Small differences between sector and regional breakdowns due to non-regional/sectoral allocatable flows.

In addition, 2017-2020 yearly average for IEA *End-use Energy Efficiency* are considered (WEI 2021).

Minor adjustments to match IEA and IPCC regions applied based on CPI pro-rata allocation. Total

Needs: See Table 15.4. Regional breakdown of needs: For *Electricity* based on IAM output for Non-Biomass renewable (mean C1:C3) plus incremental investment needs for T&D and Storage (mean C1:C3 less mean C5:C7) (see Table 15.2, 15.3., except C6 and C7). For *Energy Efficiency* based on IRENA

Transforming Energy Scenario (TES) and adjusted to IPCC regional categories based on GDP. *Agriculture and Forestry* based on chapter 7.4 analysis and additional needs based on GDP. *Transport*

investments for rail investment based on GIO rail investment needs per country and IRENA regional breakdown for total energy efficiency for needs for EV charging infrastructure, transport energy efficiency, and costs of batteries of EVs with adjustments to IPCC regional categories based on Energy Efficiency pro rata.

Sectoral considerations. The renewable energy sector attracted the highest level of funding in absolute and relative terms with business models in generation being proven and rapidly falling technology costs driving the competitiveness of solar photovoltaic and on-shore wind even without taking account the mitigation component (FS-UNEP Centre and BNEF 2019; IRENA 2020a). This investment activity comes in line with the first generation of NDCs and their heavy focus on mitigation opportunities in the renewable energy sector (Pauw et al. 2016; Schletz et al. 2017). Still, the investment gap tends to remain stable with flows over the past years not showing an upward trend.

Comparing annual average total investments in global fuel supply and the power sector of approximately 1.61 trillion USD yr⁻¹ in 2019 (IEA 2020a) to the investment in the Stated Policies Scenario (approximately 1.84 trillion USD yr⁻¹) and the Sustainable Development Scenario (approximately 1.91 trillion USD yr⁻¹) in 2030 underlines the required shift of existing capital

1 investment from fossil to renewables even more than the need to increase sector allocations (Granoff et
2 al. 2016; McCollum et al. 2018).

3 Ensuring access to the heavily regulated electricity markets is a key driver for an accelerated private
4 sector engagement (IFC 2016; FS-UNEP Centre and BNEF 2018; REN21 2019) with phasing out of
5 support schemes and regulatory uncertainty being a major driver for reduced investment volumes in
6 various regional markets in the past years (FS-UNEP Centre and BNEF 2015, 2016, 2017, 2018, 2020).
7 Strategic investors and corporate investments by utilities dominate the investment activity in developed
8 countries and countries in transition (BNEF 2019) based on the competitiveness of renewable energy
9 sources. Reasonable auction results based on a substantial private-sector competition for investments
10 have also been achieved in selected developing countries driven by rather standardised contract
11 structures and the increased availability of risk mitigation instruments addressing political/regulatory
12 risks and home bias constraints (FS-UNEP Centre and BNEF 2019; IRENA 2020a). DFI climate
13 portfolios tend to be driven by concessional loans for renewable energy generation assets with equity
14 often being provided by (semi-) commercial investors (see Section 15.3) which will have to change to
15 accelerate renewable energy investment activity.

16 Given the wide range of estimates on current investment flows into energy efficiency, substantial
17 uncertainty exists with regard to the magnitude of the investment gaps. While CPI publishes investment
18 levels of 44 billion in 2019 and 26 billion in 2020) for energy efficiency, counting majorly international
19 flows, IEA results come in at a much higher level of more than annually 250bn USD between 2017 and
20 2020 (IEA 2021c) and (IRENA 2020c) estimates energy efficiency investments in buildings between
21 2017-2019 at an average of 139 bn USD yr⁻¹.

22 Public sector investments in the transport sector have increased significantly in the past years reflecting
23 the increased interest of capital markets in renewable energy and the efficient and corresponding
24 reallocation of public funding. Provision of funding by capital markets for public transport
25 infrastructure among others heavily depend on suitable financing vehicles and increased funding for
26 development of projects with a low level of standardization (OECD, 2015a).

27 Both IRENA and IEA include only incremental costs of EVs in their estimates on needs while CPI,
28 when measuring actual flows, includes those at full costs. Total private flows for EVs included in CPI
29 numbers amount to 41bn USD in 2018 (Buchner et al. 2019), representing more than 80% of private
30 sector finance into the transport sector around one third of total, public and private, funding to the
31 transport sector in 2018. This likely results in an underestimation of the financing gap – in addition to
32 the fact that estimates for investment needs for rail infrastructure are only available for selected
33 countries.

34 Current funding of land-based mitigation options is less than 1 billion USD yr⁻¹ representing only 2.5%
35 of climate mitigation funding, significantly below the potential proportional contribution (Buchner et
36 al. 2019). A stronger focus on deforestation-free value chain, including a stronger reflection in
37 taxonomies and financial sector investment decision processes are necessary to *ensure* an alignment of
38 financial flows with the LTGG. Taking into account the specifics of land-based mitigation (in particular
39 long investment horizons, strong dependency on the monetization of mitigation effects, strong public
40 sector involvement) a significant scale-up of commercial funding to the sector can hardly be expected
41 in absence of strong climate policies (Clark et al. 2018). Agriculture is likely to develop more potential
42 to mobilise private finance than the forest sector given its strong linkage to food security and hunger
43 and shorter payback periods. The significant gap in land-based mitigation finance also indicates the
44 crucial lack of finance to the bottom of the pyramid.

45 Agricultural support is an important source of distortions to agricultural incentives in both rich and poor
46 countries (Mamun et al. 2019) ranging from largest component of the support, market price supports,
47 increased gross revenue to farmers as a result of higher prices due to market barriers created by

1 government policies, to production payments and other support including input subsidy (e.g. fertilizer
2 subsidy) (Searchinger et al. 2020). 600 billion USD of annual governmental support for agriculture in
3 the OECD database contributes only modestly to the related objectives of boosting crop yields and just
4 transition (Searchinger et al. 2020). A review of (NDCs of 40 developing countries which submitted a
5 NDC to the UNFCCC Interim NDC Registry by April 2017, and include within their NDC efforts to
6 REDD+ via support from the UN-REDD Programme and/or World Bank Forest Carbon Partnership
7 Facility) indicates that none of the countries reviewed mention fiscal policy reform of existing finance
8 flows to agricultural commodity production or other publicly supported programmes that affect the
9 direct and underlying drivers of land use conversion (Kissinger et al. 2019).

10 **Analysis by region and type of economy.** The analysis of gaps by type of economy illustrates the
11 challenge for developing countries. Estimated mitigation financing needs as percentage of current GDP
12 (USD₂₀₁₅) comes in at around 2-4% for developed countries, and around 5-10% for developing countries
13 (see Figure 15.4) (*high confidence*). Climate finance flows have to increase by factor 4-8 in developing
14 countries and 2-5 in developed countries. This disparity is further exacerbated when considering
15 adaptation, infrastructure and SDG related investment needs (Hourcade et al. 2021a) (*high confidence*).
16 However, differences across developing countries are significant. Flows to Eastern Asia, with its
17 average flows of 269 billion USD being dominated by China (more than 95% of total mitigation flows
18 to Eastern Asia), would have to increase by a factor of 2-4, a comparable level to developed countries.
19 Section 15.6.2 elaborates on outlooks with regard to fiscal space and ability to tap capital markets, in
20 particular for developing countries. In particular, attention must accelerate on low-income Africa. This
21 large continent currently contributes very little to global emissions, but its rapidly rising energy
22 demands and renewable energy potential versus its growing reliance on fossil fuels and 'cheap' biomass
23 (especially fuelwood for cooking and charcoal with impacts on deforestation) amid fast-rising
24 urbanization makes it imperative that institutional investors and policy-makers recognise the very large
25 'leap-frog' potential for the renewable energy transition as well as risks of lock-in effects in
26 infrastructure more general in Africa that is critical to hold the global temperatures rise to well below
27 2°C in the longer-term (2020–2050). Overlooking this transition opportunity, rivalling China, India, US
28 and Europe, would be costly. Policies centred around the accelerated development of local capital
29 markets for energy transitions - with support from external grants, supra-national guarantees and
30 recognition of carbon remediation assets - are crucial options here, as in other low-income countries
31 and regional settings. Notably, climate finance flows to African countries might have even decreased
32 by about one fifth for mitigation technology deployment (stagnated for adaptation between 2017 and
33 2020), widening the finance gap in African countries in the recent years (*high confidence*).

34 Over 80% of climate finance is reported to originate and stay within borders, and even higher for private
35 climate flows (over 90%) (Boissinot et al. 2016). There are multiple reasons for such 'home bias' in
36 finance - national policy support, differences in regulatory standards, exchange rate, political and
37 governance risks, as well as information market failures. The extensive home bias means that even if
38 national actions are announced and intended to be implemented unilaterally and voluntarily, the ability
39 to implement them requires access to climate finance which are constrained by the relative ability of
40 financial and capital markets at home to provide such financing, and access to global capital markets
41 that requires supporting institutional policies in source countries. 'Enabling' public policies and actions
42 locally (cities, states, countries and regions), to reduce investment risks and boost domestic climate
43 capital markets financing, and to enlarge the pool of external climate financing sources with policy
44 support from source capital countries thus matter at a general level. The biggest challenge in climate
45 finance is likely to be in developing countries, even in the presence of enabling policies and quite apart
46 from any other considerations such as equity and climate justice (Klinsky et al. 2017) or questions about
47 the equitable allocations of future 'climate budgets' (Gignac and Matthews 2015). The differentiation
48 between developed and developing countries matter most on financing. Most developed countries have
49 already achieved very high levels of incomes, have the largest pool of capital stock and financial capital
50 (which can be more easily redeployed within these countries given the 'home bias' of financial

1 markets), the most well-developed financial markets and the highest sovereign credit-ratings, in
2 addition to starting with very high levels of per capita carbon consumption - factors that should allow
3 the fastest adjustment to low carbon investments and transition in these countries from domestic policies
4 alone. The financial and economic circumstances are the opposite for virtually all developing countries,
5 even within a heterogeneity of circumstances across countries. The dilemma, however, is that the fastest
6 rates of the expected increase in future carbon emissions are in developing countries. The biggest
7 challenge of climate finance globally is thus likely to be the constraints to climate financing because of
8 the opportunity costs and relative under-development of capital markets and financing constraints (and
9 costs) at home in developing countries, and the relative availability or absence of adequate financing
10 policy support internationally from developed countries. The Paris Agreement and commitment by
11 developed countries to support the climate financing needs of developing countries thus continue to
12 matter a great deal.

13 **Soft costs / Institutional capacity** (Osama et al. 2021). Most funding needs assessments focus on
14 technology costs and ignore the cascade of financing needs as outlined above. International grant
15 funding or national budget allocations for soft costs like the creation of a regulatory environment can
16 be prerequisite for the supply of commercial financing for the deployment of technologies. Such critical
17 funding needs might represent a small share of overall investment needs but current (relatively small)
18 gaps in funding of policy reforms can hinder/delay deployment of large volumes of funding in later
19 years. The role, as well as the approximate volumes of such required timely international grant funding
20 or national budget allocations, appear underestimated in research. The numbers available for the
21 creation of an enabling environment for medium-sized RE projects in Uganda (GET FiT Uganda) are
22 illustrative only and cannot be transferred as assumptions to other countries without taking into account
23 potentially varying starting points in terms of institutional readiness, pipelines as well as the general
24 business environment. GET FiT Uganda supported 170 MWp of medium-scale RE capacity triggering
25 investments of 453 million USD (GET FiT Uganda 2018), international results-based incremental cost
26 support amounted to 92 million USD and project preparation, technical assistance, as well as
27 implementation support, required 8 million USD excluding support from national agencies.

28 There is strong evidence of the correlation between institutional capacity of countries and international
29 climate finance flows towards those economies (Adenle et al. 2017; Stender et al. 2019) and a strong
30 need for robust institutional capacity to manage the transformation in a sustainable and human rights
31 based way (Duyck et al. 2018). One example to consider unaddressed social concerns, is the ongoing
32 call for feedback by the European Commission and its platform on sustainable finance. It argues for a
33 social taxonomy, that can support the identification of financing opportunities of economic activities
34 contributing to social objectives (European Commission 2021b). SEforAll has highlighted the issue of
35 investments not going to the countries with the greatest need, also partly driven by institutional capacity
36 levels (SEforALL and CPI 2020). Also, most of the developing countries NDCs are conditional upon
37 international support for capacity building (Pauw et al. 2020). The Climate Technology Centre and
38 Network (CTCN) was created as an operational arm of the UNFCCC Technology Mechanism with the
39 mandate to respond to requests from developing countries. Initial evaluations of the mechanism
40 underpin its importance and value for developing countries but stress long lead times and predictability
41 of future international public funding to maintain operations as key challenges (UNFCCC 2017;
42 DANIDA 2018). While limited pipelines, limited absorptive capacities as well as restricted institutional
43 capacity of countries being often stated as challenge for an accelerated deployment of funding (Adenle
44 et al. 2017), the question remains on the role of international public climate finance to address this gap
45 and whether a concrete current financing gap exists for patient institutional capacity building. While
46 current short-term, mostly project-related capacity building often fails to meet needs but alternative,
47 well-structured patient interventions and funding could play an important role (Saldanha 2006; Hope
48 2011) accepting other barriers than funding playing a role as well. One reason why international public
49 climate funding is not sufficiently directed to such needs might be the complexity in measuring
50 intangible, direct outcomes like improved institutional capacity (Clark et al. 2018).

1 **Early stage/Venture capital funding/Pilot project funding** Early-stage companies in impact
2 investment sectors with business solutions can contribute positively to climate impact. Figure SPM.8
3 highlights the need for new business models facilitating parts of the behavioural change. Also, SE4All
4 has underpinned the need for an expansion of available business models to achieve universal access
5 (SEforALL and CPI 2020). Further research and development needs range from resource efficiency of
6 proven technologies and next generation technologies but also new technologies (see Chapter 16).
7 Access to early stage funding remains critical with performance in recent years being weak (Gaddy
8 et al. 2016). This historically weak performance of clean tech start-ups burdens the interest of investors
9 in the sector on the one hand and discourage experienced executive talent (Wang and Yee 2020).
10 Besides that, the concentration of VC markets in the US, Europe and India represents a major challenge
11 (FS-UNEP Centre and BNEF 2019; Statistica 2021). With regard to commercial-scale demonstration
12 projects, IEA estimates a need of 90 USD billion of public sector funding before 2030 having around
13 25 billion USD already planned by governments to 2030 (IEA 2021c).

14 **Need parallel rather than sequential investment decisions.** The needs and gaps assessment does not
15 include upstream investment needs required to facilitate the technology deployment as foreseen in the
16 scenarios presented above. For example, for their transforming energy scenario IRENA estimates the
17 number of EVs to increase from around 8m units in 2019 to 269m units in 2030 (IRENA 2020c). This
18 would require investments in battery factories amounting to approximately 207 USD billion with further
19 investment requirements in the value chain (IRENA 2020d). This illustrates the extent of parallel
20 investments based on goals rather than concrete regulatory interventions and/or demand and poses a
21 problem of up-front investment risks for each industry in the chain in the absence of certainty of the
22 presence of parallel decisions in the upstream and downstream links in the chain. This is a typical
23 element of the ‘valley of the death’ of innovation (Scherer et al. 2000; Åhman et al. 2017). It discourages
24 risk-taking and slows-down the learning-by-doing processes, economies of scale and increasing returns
25 to adoption needed for lowering the costs of systemic technical change (Kahouli-Brahmi 2009; Weiss
26 et al. 2010). Implications on risk perception, financing costs as well as investment decision making
27 processes and ultimately on feasibility are rarely considered.

28 **Finance for adaptation and resilience.** As explained early the reduction of the infrastructure gap to
29 increase the societies’ resilience and the implementation of the NAPs of will require more and higher
30 levels of sustained financing. Activities mobilized for adaptation and resilience are often non
31 marketable and their funding will continue coming from the public sector noted by (Murphy and Parry
32 2020) and, at the international level from grants based technical assistance or through budgetary support
33 or basket funding for large projects/program or sector wide approaches or multilateral funding under
34 (Non-)UNFCCC² are also anticipate supporting NAP implementation - particularly those involved
35 incremental costs and co-benefits, which will include sectoral approach such as water, energy,
36 infrastructures, food production. According to the UNFCCC, ‘in 2015–2016, 3 per cent of international
37 public adaptation finance flows was supplied by multilateral climate funds, while 84 per cent came from
38 development finance institutions and 13 per cent from other government sources’ (UNFCCC 2019c).
39 Comprehensive reporting on adaptation finance by (Murphy and Parry 2020) and (Buchner et al. 2019)
40 argues that flows of finance for adaptation action in developing countries in 2017 and 2018 were
41 estimated to be approximately USD 30 billion; this plus an additional estimated flow of USD 12 billion
42 for dual adaptation and mitigation actions totalled USD 42 billion accounting for 7.25% of the total
43 estimated international public and private flows of climate finance (Buchner et al. 2019). They are far
44 below the financing needs given in 15.4. To date, the private sector has limited involvement in NAPs

FOOTNOTE² Those under the UNFCCC such as the GCF through its 3 million USD per country readiness and preparatory support programme, the LDCF and the SCCF and the PPCR and ASAP are focused on supporting the preparatory process of the NAPs. But the Adaptation Fund will support the implementation of concrete projects up to 10 million USD per country.

1 and adaptation projects and planning but can be involved through public-private partnership (discussed
2 in section 15.6.2.1) and other incentives provided by governments (Schmidt-Traub and Sachs 2015;
3 Koh et al. 2016; Druce et al. 2016; UNEP 2016; NAP Global Network 2017; Murphy and Parry 2020)
4 and innovative private financing mechanisms such as green and blue bonds. However, adaptation
5 financing is only about 2% of the share of green bond financing raised up to June 2019 (UNFCCC
6 2019c)³, whereas it is about 10% of sovereign green bonds raised (UNFCCC 2019d). (Tuhkanen
7 2020a), in a detailed review of green bond issuance in the Environmental Finance Data base 2019,
8 found that between March 2010 to April 2019, ‘5% of all green bonds issued were categorized as
9 adaptation and that ‘the private sector accounts for a significant proportion of adaptation-related green
10 bond issuances’ (p.11). However, citing (GIZ 2017b; Nicol et al. 2017, 2018a) (Tuhkanen 2020b)
11 highlights that there is scepticism about this stream of funding for adaptation due to the factors that has
12 thus far limited the private sector’s involvement in adaptation: lack of resilience-related revenue
13 streams, the small-scale of some adaptation projects and the overall “intangibility” of funding
14 adaptation projects,’ (p.9). (Larsen et al. 2019)

15 Financing for resilience is limited unpredictable, fragmented and focused on few projects or sectors and
16 short term as opposed to programmatic and long-term (10–15 years) funding to build resilience (ISDR
17 2009, 2011; Kellett and Peters 2014; Watson et al. 2015). Market-based mechanisms are available but
18 not equally accessible to all developing countries, particularly SIDS and LDCs and such mechanisms
19 can undermine debt sustainability (OECD and World Bank 2016).. While resilience financing is mainly
20 grant-funding, concessional loans are increasing substantially and are key sources of financing for
21 disaster and resilience, particularly for upper-middle-income countries (OECD and World Bank 2016).
22 The combination of these trends can contribute to greater levels of indebtedness among many
23 developing countries many of who are already at or approaching debt distress.

24 Social protection systems can be linked with a number of the instruments already considered: reserve
25 funds, insurance and catastrophe bonds, regional risk-sharing facilities, contingent credit, in addition to
26 traditional international aid and disaster response. (Hallegatte et al. 2017) recommend combining
27 adaptive social protection with financial instruments in a consistent policy package, which includes
28 financial instruments to deliver adequate liquidity and contingency plans for the disbursement of funds
29 post-disaster. Challenges related to financing residual climate-related losses and damages are
30 particularly high for developing countries. Financing losses and damages from extreme events requires
31 rapid pay-outs; the cost of financing for many developing countries is already quite high; and the
32 expense of risk financing is expected to increase as disasters become more frequent, intense and more
33 costly not only due to climate change but also due to higher levels of exposure. Addressing both extreme
34 and slow onset climate impacts requires designing adequate financial protection systems for reaching
35 the most vulnerable. Moreover, some fraction of losses and damages, both material and non-material,
36 are not commonly valued in monetary terms [non-economic loss] and hence financing requirements are
37 hard to estimate. These non-market-based residual impacts include loss of cultural identity, sacred
38 places, human health and lives (Paul 2019; Serdeczny 2019).

39

40 **15.6 Approaches to accelerate alignment of financial flows with long-term** 41 **global goals**

42 Near-term actions to shift the financial system over the next decade are critically important and possible
43 with globally coordinated efforts. Taking into account the inertia of the financial system as well as the

FOOTNOTE³ According to climate bonds initiative, total green bond finance raised in 2018 was 168.5 billion USD across 44 countries (UNFCCC 2019c).

1 magnitude of the challenge to align financial flows with the long-term global goals, fast action is
 2 required to ensure the readiness of the financial sector as an enabler of the transition (*high confidence*).
 3 The following subsections elaborate on key areas which can have a catalytic effect in terms of
 4 addressing existing barriers – besides political leadership and interventions discussed in other Chapters
 5 of AR6.

6

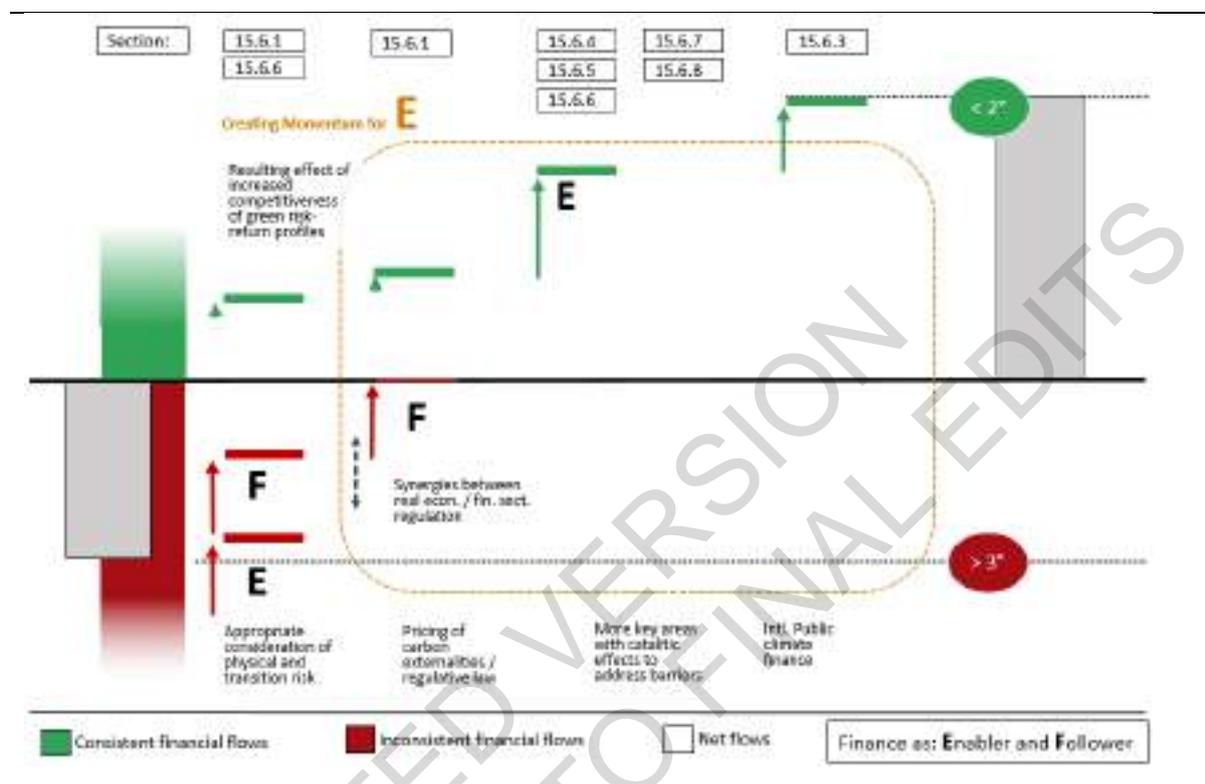

Figure 15.5 Visual abstract to address financing gaps in Section 15.6

7 Addressing knowledge gaps with regard to climate risk analysis and transparency will be one key driver
 8 for more appropriate climate risk assessment and efficient capital allocation (15.6.1), efficient enabling
 9 environments support the reduction of financing costs and reduce dependency on public financing
 10 (15.6.2), a revised common understanding of debt sustainability, including also negative implications
 11 of deferred climate investments on future GDP, particularly stranded assets and resources to be
 12 compensated, can facilitate the stronger access to public climate finance, domestically and
 13 internationally (15.6.3), climate risk pooling and insurance approaches are a key element of financing
 14 of a just transition (15.6.4), the supply of finance to a widened focus on relevant actors can ensure
 15 transformational climate action at all levels (15.6.5), new green asset classes and financial products can
 16 attract the attention of capital markets and support the scale up of financing by providing standardised
 17 investment opportunities which can be well integrated in existing investment processes (15.6.6), a
 18 stronger focus on the development of local capital markets can help mobilizing new investor groups
 19 and to some extent mitigate home bias effects (15.6.7), new business models and financing approaches
 20 can help to overcome barriers related to transactions costs by aggregating and/or transferring financing
 21 needs and establish supply of finance for needs of stakeholder groups lacking financial inclusion
 22 (15.6.8).

1 15.6.1 Address knowledge gaps with regard to climate risk analysis and transparency

2 **Climate change as a source of financial risk.** Achieving climate mitigation and adaptation objectives
3 requires ambitious climate finance flows in the near-term, i.e. 5-10 years ahead. However, knowledge
4 gaps in the assessment of climate-related financial risk are a key barrier to such climate finance flows.
5 Therefore, this section discusses the main knowledge gaps that are currently being addressed in the
6 literature and those that remain outstanding

7 Climate-related financial risk is meant here as the potential adverse impact of climate change on the
8 value of financial assets. A recent but remarkable development since AR5 is that climate change has
9 been explicitly recognised by financial supervisors as a source of financial risk that matters both for
10 financial institutions and citizens' savings (Bolton et al. 2020). Previously, climate change was mostly
11 regarded in the finance community only as an ethical issue. The reasons why climate change implies
12 financial risk are not new and are discussed more in detail below. What is new is that climate enters
13 now as a factor in the assessment of financial institutions' risk (e.g. such as the European Central Bank
14 or the European Banking Authority) and credit rating (see also Section 15.6.3) and, going forward, into
15 stress-test exercises. This implies changes in incentives of the supervised financial actors, both public
16 and private, and thus changes in the landscape of mitigation action by generating a new potential for
17 climate finance flows. However, critical knowledge gaps remain. In particular, the underestimation of
18 climate-related financial risk by public and private financial actors can explain that the current
19 allocation of capital among financial institutions is often inconsistent with the mitigation objectives
20 (Rempel et al. 2020). Moreover, even a correct assessment of risk, which could provide incentives for
21 divesting from carbon-intensive activities, does not necessarily lead to investing in the technical options
22 needed for deep decarbonisation. Therefore, understanding the dynamics of the low carbon transition
23 require to fill in at the same time gaps about risk and gaps about investments in enabling activities in a
24 broader sense.

25 **Physical risk.** On the one hand, unmitigated climate change implies an increased potential for adverse
26 socio-economic impacts especially in more exposed economic activities and areas (*high*
27 *confidence*). Accordingly, *physical risk* refers to the component of financial risk associated with the
28 adverse physical impact of hazards related to climate change (e.g., extreme weather events or sea level
29 rise) on the financial value of assets such as industrial plants or real estate. In turn, these losses can
30 translate into losses on the values of financial assets issued by exposed companies (e.g., equity/bonds)
31 and or sovereign entities as well as losses for insurance companies. The assessment of climate financial
32 physical risks poses both challenges in terms of data, methods and scenarios. It requires to cross-
33 match scenarios of climate-related hazards at granular geographical scale, with the geolocation and
34 financial value of physical assets. The relationship between the value of physical assets (such as
35 plants or real estate) and the financial value of securities issued by the owners of those assets is not
36 straightforward. Further, the repercussion of climate related hazards on sovereign risk should also be
37 accounted for.

38 **Transition risks and opportunities.** On the other hand, the mitigation of climate change, by means of
39 a transition to a low-carbon economy, requires a transformation of the energy and production system at
40 a pace and scale that implies adverse impacts on a range of economic activities, but also opportunities
41 for some other activities (*high confidence*). If these impacts are factored in by financial markets, they
42 are reflected in the value of financial assets. Thus, *transition risks and opportunities* refer to the
43 component of financial risk (opportunities) associated with negative (positive) adjustments in assets'
44 values resulting directly or indirectly from the low-carbon transition.

45 The concepts of *carbon-stranded assets* (see e.g.(Leaton and Sussams 2011), and *orderly vs. disorderly*
46 *transition* (Sussams et al. 2015) emerged in the NGO community, have provided powerful metaphors

1 to conceptualise transition risks and have evolved into concepts used also by financial supervisors
2 (NGFS 2019) and academics. The term carbon stranded assets refer to fossil-fuel-related assets (fuel
3 or equipment) that become unproductive. An *orderly transition* is defined here as a situation in which
4 market players are able to fully anticipate the price adjustments that could arise from the transition. In
5 this case, there would still be losses associated with stranded assets, but it would be possible for market
6 players to spread losses over time and plan ahead. In contrast, a *disorderly transition* is defined here as
7 a situation in which a transition to a low carbon economy on a 2C° path is achieved (i.e., by about 2040),
8 but the impact of climate policies in terms of reallocation of capital into low-carbon activities and the
9 corresponding adjustment in prices of financial assets (e.g. bonds and equity shares) is large, sudden
10 and not fully anticipated by market players and investors. Note the impact could be unanticipated even
11 if the date of the introduction is known in advance by the market players. There are several reasons why
12 such adjustments could occur. One simple argument is that the political economy of the transition is
13 characterised by forces in different directions, including opposing interests within the industry,
14 mounting pressure from social awareness of unmitigated climate risks. Politics will have to find a
15 synthesis and the outcome could remain uncertain until it suddenly unravels. Note also that, in order to
16 be relevant for financial risk, the disorderly transition does not need to be a catastrophic scenario in
17 terms of the fabric of markets. It also does not automatically entail systemic risk, as discussed further
18 down. Knowledge gaps in this area are related to emerging questions, including: What are, in detail, the
19 transmission channels of physical and transition risk? How to assess the magnitude of the exposure to
20 these risks for financial institutions and ultimately for people's savings? How do transition risk and
21 opportunities depend on the future scenarios of climate change and climate policies? How to deal with
22 the intrinsic uncertainty around the scenarios? To what extent, an underestimation of climate-related
23 financial risk, could feed back on the alignment of climate finance flows and hamper the low-carbon
24 transition? Should climate risk be explicitly accounted for in regulatory frameworks for
25 financial institutions, such as Basel III for banks and national frameworks for insurance?
26 What lessons from the 2008 financial crisis are relevant here, regarding moral hazard and the
27 trustworthiness of credit risk ratings? The attention of both practitioners and the scientific
28 community to these questions has grown since the Paris Agreement. In the following we review some
29 of the findings from the literature, but the field is relatively young and many of the questions are still
30 open.⁴ Nordic countries (FinansNorge et al. 2013). Damages from climate change are expected to
31 escalate dramatically in Europe (Forzieri et al. 2018) and in some EU countries there is already some
32 evidence that banks, anticipating possible losses on their loan books, lend proportionally less to

33 **Assessment of physical risk.** There is a literature on estimates of economic losses on physical assets (see
34 respective chapter in WGII). Here we discuss some figures and mechanisms that are relevant for the financial
35 system. Significant cost increases have been observed related to increases in frequency and
36 magnitude of extreme events (see Section 15.4.2) (*high confidence*). At the global level, the expected
37 'climate value at risk' (climate VaR) of financial assets has been estimated to be 1.8% along a
38 business-as-usual emissions path (Dietz et al. 2016), with however, a concentration of risk in the tail
39 (e.g. 99th VaR equals to 16.9%, or 24.2 trillion USD, in 2016). Climate-related impacts are estimated
40 to increase the frequency of banking crises (up over 200% across scenarios) while rescuing insolvent
41 banks could increase the ratio of public debt to gross domestic product by a factor of 2 (Lamperti et al.
42 2019). Further assessments of physical risk for financial assets (Mandel 2020), accounting in particular
43 for the propagation of losses through financial networks, estimate global yearly GDP losses at 7.1%
44 (1.13%) in 2080, without adaptation (with adaptation), the former corresponding to a 10-fold increase
45 with respect to the current yearly losses (0.76% of global GDP). Finally, climate physical risk can

FOOTNOTE⁴ In the context, while belonging to grey literature, reports from financial supervisors or non-academic stakeholders, can be of interest, for what they document in terms of changes in perception and incentives among the market players and hence of the dynamics of climate finance flows.

1 impact on the value of sovereign **bonds** (one of the top asset classes by size), in particular for vulnerable
2 countries (Volz et al. 2020).

3 Insurance payouts for catastrophes have increased significantly over the last 10 years, with dramatic
4 cost spikes in years with multiple major catastrophes (such as in 2018 with hurricanes Harvey,
5 Irma, and Maria). This trend is expected to continue. The indirect costs of climate-related flooding
6 event can be up to 50% of the total costs, the majority of which is not covered by insurance (Alnes
7 et al. 2018) (see chapter 15.6.4). The gap between total damage losses and insurance payouts has
8 increased over the past 10 years (Swiss Re Institute 2019). Indeed, the probability of 'extreme but
9 plausible' scenarios will be progressively revised upwards in the 'value at risk' (VaR). As a result it
10 becomes more difficult to find financial actors willing to provide insurance as it was observed for real
11 estate in relation to flood and wildfires in California (Ouazad and Kahn 2019). This progressive
12 adjustment would keep the financial system safe (Climate-Related Market Risk Subcommittee 2020;
13 Keenan and Bradt 2020), but transfer to taxpayers the onus of damage compensation and the funding
14 of adaptation investments (OECD 2021c) as well as build up latent liabilities.

15 **Assessment of transition risk**

16 Carbon stranded assets. Fossil fuel reserve and resource estimates exceed in equivalent quantity of CO₂
17 with virtual certainty the carbon budget available to reach a 1.5°C and 2°C targets (Meinshausen et al.
18 2009; McGlade and Ekins 2015; Millar et al. 2017) (*high confidence*). In relative terms, stranded assets
19 of fossil-fuel companies amount to 82% of global coal reserves, 49% of global gas reserves and 33%
20 of global oil reserves (McGlade and Ekins 2015). This suggests that only less than the whole quantity of
21 fossil fuels currently valued (either currently extracted, waiting for extraction as reserves or assets on
22 company balance sheets) can yield economic return if the carbon budget is respected. The devaluation
23 of fossil fuel assets imply financial losses for both the public sector (see Section 15.6.8) and the private
24 sector (Coffin and Grant 2019). Global estimates of potential stranded fossil fuel assets amount to at
25 least 1 trillion, based on ongoing low-carbon technology trends and in the absence of climate
26 policies (cumulated to 2035 with 10% discount rate applied; 8 trillion USD without discounting
27 (Mercure et al. 2018a). With worldwide climate policies to achieve the 2°C target with 75%
28 likelihood, this could increase to over 4 trillion USD (until 2035, 10% discount rate; 12 trillion USD
29 without discounting). Other estimates indicate 8–15 trillion USD (until 2050, 5% discount rate, (Bauer
30 et al. 2015)) and 185 trillion USD (cumulated to year 2115 using combined social and private discount
31 rate; (Linquiti and Cogswell 2016)). However the geographical distribution of potential stranded
32 fossil fuel assets (also called 'unburnable carbon') is not even across the world due to differences
33 in production costs (McGlade and Ekins 2015). In this context, a delayed deployment of climate
34 funding and consequently limited alignment of investment activity with the Paris Agreement tend to
35 strengthen carbon and thus to increase the magnitude of stranded assets.

36 **Assets directly and indirectly exposed to transition risk.** In terms of types of assets and economic
37 activities, the focus of estimates of carbon stranded assets, tend to be on physical reserves of fossil fuel
38 (e.g., oil fields) and sometimes financial assets of fossil-fuel companies (see (van der Ploeg and Rezai
39 2020)). However, a precondition for a broader analysis of transition risks and opportunities is to go
40 beyond the narrative of stranded assets and to consider a classification of sectors of all the economic
41 activities that could be affected (Monasterolo 2020). This, in turn depends on their direct or indirect
42 role in the GHG value chain, their level of substitutability with respect to fossil fuel and their role in
43 the policy landscape. Moreover, such a classification needs to be replicable and comparable across
44 portfolios and jurisdictions. One classification that meets these criteria is the Climate Policy Relevant
45 Sectors (CPRS) (Battiston et al. 2017) which has been used in several studies by financial supervisors
46 (EIOPA 2018; ECB 2019; EBA 2020; ESMA 2020). The CPRS classification builds on the
47 international classification of economic activities (ISIC) to map the most granular level (4 digits) into
48 a small set of categories characterised by differing types of risk: fossil-fuel (i.e. all activities whose

1 revenues depends mostly and directly on fossil-fuel, including concession of reserves and operating
2 industrial plants for extraction and refinement); electricity (affected in terms of input but that can in
3 principle diversify their energy sources); energy intensive (e.g. steel or cement production plants,
4 automotive manufacturing plants), which are affected in terms of energy cost but not in terms of the main
5 input); transport and buildings (affected in terms of both energy sources and specific policies). All
6 financial assets (e.g. bonds, equity shares, loans) having as issuers or counterparties firms whose
7 revenues depends significantly on the above activities are thus potentially exposed to transition risks
8 and opportunities. Further, investors' portfolios have to be part of the analysis since changes in financial
9 assets values affect the stability of financial institutions and can thus feed back into the transition
10 dynamics itself (e.g. through cost of debt for firms and through costs for assisting the financial
11 sector). One outstanding challenge for the analysis of investors' exposure to climate risks is the
12 difficulty to gather granular and standardised information on the breakdown of non-financial firms'
13 revenues and capex in terms of low/high-carbon activities (*high confidence*).

14 Several financial supervisors have conducted assessments of transition risk for the financial system at
15 the regional level. For instance, the European Central Bank (ECB) reported preliminary estimates of
16 aggregate exposures of financial institutions to CPRS relative to their total debt securities holdings, as
17 ranging between 1% for banks to about 9% for investment funds (ECB 2019). The European Insurance
18 and Occupational Pensions Authority (EIOPA) reported aggregate exposures to CPRS of EU insurance
19 companies at about 13% of their total securities holdings (EIOPA 2018). Further analyses on the EU
20 securities holdings indicate that among financial investments in bonds issued by non-financial
21 corporations, EU institutions hold exposures to CPRS ranging between 36.8% for investment funds to
22 47.7% for insurance corporations; analogous figures for equity holdings range from 36.4% for banks
23 to 43.1% for pension funds (Alessi et al. 2019). Another study indicates that losses on EU insurance
24 portfolios of sovereign bonds could reach up to 1%, in conservative scenarios (Battiston et al. 2019).

25 Given the magnitude of the assets that are potentially exposed, reported in the previously cited studies,
26 a delayed or uncoordinated transition risk can have implications for financial stability not only at the
27 level of individual financial institutions, but also at the macro-level. The possible systemic nature of
28 climate financial risk has been highlighted on the basis of general equilibrium economic analysis (Stern
29 and Stiglitz 2021).

30 Some financial authorities recognize that Climate change represents a major source of systemic risk,
31 particularly for banks with portfolios concentrated in certain economic sectors or geographical areas
32 (de Guindos 2021). Specifically, the concern that central banks would have to act as "climate rescuers
33 of last resort" in a systemic financial crisis stemming from some combination of physical and transition
34 risk has been raised in the financial supervisor community (Bolton et al. 2020). The systemic nature of
35 climate risk is reinforced by the possible presence of moral hazard. Indeed, if many enough financial
36 actors have an incentive to downplay climate-related financial risk, then systemic risk builds up in the
37 financial system eventually materialising for tax payers (Climate-Related Market Risk Subcommittee
38 2020). While such type of risk may go undetected to standard market indicators for a while, it can
39 materialise with a time delay, similarly to the developments observed in the run up of the 2008 financial
40 crisis.

41 These considerations are part of an ongoing discussion on whether the current financial frameworks,
42 including Basel III, should incorporate explicitly climate risk as a systemic risk. In particular, the
43 challenges in quantifying the extent of climate risk, reviewed in this section, especially if risk is
44 systemic, raise the question whether a combination of quantitative and qualitative restrictions on banks'
45 portfolios could be put in place to limit the build-up of climate risks (Baranović et al. 2021).

1 **Endogeneity of risk and multiplicity of scenarios.** One fundamental challenge is that climate-related
2 financial risk is endogenous (*high confidence*). This means that the perception of the risk changes the
3 risk itself, unlike most contexts of financial risk. Indeed, transition risk depends on whether
4 governments and firms continue on a business-as-usual pathway (i.e. misaligned with the Paris
5 Agreement targets) or engage on a climate mitigation pathway. But the realisation of the transition
6 pathway depends itself on how, collectively, society, including financial investors and supervisors,
7 perceive the risk of taking / not taking the transition scenario. The circularity between perception of
8 risk and realisation of the scenario simplifies first of all those multiple scenarios are possible, and that
9 which scenario is ultimately realised can depend on policy action. The coordination problem associated
10 also with low-carbon investments opportunities increases the uncertainty. Further, not all low-carbon
11 activities are directly functional to the transition (e.g. investments in pharmaceutical, IT companies, or
12 financial intermediaries), thus not all reallocations of capital lead to the same path.

13 In this context, probabilities of occurrence of scenarios are difficult to assess and this is important
14 because risk vary widely across the different scenarios. In this context a major challenge is the fat-tail
15 nature of physical risk. One the one hand, forecasts of climate change and its impact on humans and
16 ecosystems imply tail events (Weitzman 2014) and tipping points which cannot be overcome by model
17 consensus (Knutti 2010). On the other hand, everything else the same, costs and benefits vary
18 substantially with assumptions on agents' utility, productivity, and intertemporal discount rate, which
19 ultimately depend on philosophical and ethical considerations (see (Nordhaus 2007; Nicholas Stern
20 2008; Pindyck 2013). Thus, more knowledge is needed on the interaction of climate physical and
21 transition risk, the possible reinforcing feedbacks and transmission channels to the economy and to
22 finance. Moreover, models need to account for compound risk, i.e. the interaction of climate physical
23 and/ or transition risk with other sources of risk such as pandemics, as the COVID-19.

24 **Challenges for climate transition scenarios.** The endogeneity of risk and its associated deep
25 uncertainty implies that the standard approach to financial risk consisting of computing expected values
26 and risk based on historical values of market prices, is not adequate for climate risk (Bolton et al. 2020)
27 (*high confidence*). To address this challenge, a recent stream of work has developed an approach to
28 make use of climate policy scenarios to derive risk measures (e.g. expected shortfall) for financial
29 assets and portfolios, conditioned to scenarios of disorderly transition (Battiston et al. 2017;
30 Monasterolo and Battiston 2020; Roncoroni et al. 2020). In particular, climate policy shocks on the
31 output of low/high carbon economic activities are calculated based on trajectories of energy
32 technologies as provided by large-scale Integrated Assessment Models (Kriegler et al. 2015;
33 McCollum et al. 2018) conditioned to the introduction of specific climate policies over time. This
34 approach allows to conduct climate stress-test both at the level of financial institutions and at the level
35 of the financial system of a given jurisdiction.

36 In a similar spirit, recently, the community of financial supervisors in collaboration with the community
37 of climate economics has identified a set of climate policy scenarios, based on large-scale IAM, as
38 candidate scenarios for assessing transition risk (Monasterolo and Battiston 2020). These scenarios have
39 been used for instance, in an assessment of transition risk conducted at a national central bank (Allen
40 et al. 2020). This development is key to mainstreaming the assessment of transition risk among financial
41 institutions, but the following challenges emerge (*high confidence*). First, a consensus among financial
42 supervisors and actors on scenarios of transition risk that are too mild could lead to a systematic
43 underestimation of risk. The reason is that the default probability of leveraged financial institutions is
44 sensitive to errors in the estimation of the loss distribution and hence sensitive on the choice of
45 transition scenarios (Battiston and Monasterolo 2020). This in turn could lead to an allocation of
46 capital across low/high carbon activities that is insufficient to cater for the investment needs of the
47 low-carbon transition.

1 Second, IAM do not contain a description of the financial system in terms of actors and instruments and
2 make assumptions on agents' expectations that could be inconsistent with the nature of a disorderly
3 transition (Espagne 2018; Pollitt and Mercure 2018a; Battiston et al. 2020b). In particular, IAMs solve
4 for least cost pathways to an emissions target in 2100 (AR4 WGIII SPM Box 3), while the financial
5 sector's time horizon is much shorter and risk is an important factor in investment decision.

6 Third, the current modelling frameworks used to develop climate mitigation scenarios, which are based
7 on large-scale IAM, assume that the financial system acts always as an enabler and do not account for
8 the fact that, under some condition (i.e. if there is underestimation of climate transition risk) can also
9 act as a barrier to the transition (Battiston et al. 2020a) because it invests disproportionately more in
10 high carbon activities.

11 **Macroeconomic implications of the technological transition.** Global macroeconomic changes that
12 may affect asset prices are expected to take place as a result of a possible reduction in growth or
13 contraction of fossil fuel demand, in scenarios in which climate targets are met according to carbon
14 budgets, but also following ongoing energy efficiency changes ((Mercure et al. 2018a); see also (Clarke
15 et al. 2014)) (*high confidence*). A review of the economic mechanisms involved in the accumulation
16 of systemic risk associated to declining industries, with focus on fossil fuels, is given by (Semieniuk
17 et al. 2021). An example is the transport sector, which uses around 50% of oil extracted (IEA 2018;
18 Thomä 2018). A rapid diffusion of electric vehicles (and other alternative vehicle types), poses an
19 important risk of as it could lead to oil demand peaking before 2050 far before mid-century (Mercure
20 et al. 2018b; Mercure et al. 2021). New technologies and fuel switching in aviation, heavy industry
21 and shipping could further displace liquid fossil fuel demand (IEA 2017). A rapid diffusion of solar
22 photovoltaic could displace electricity generation based predominantly on coal and gas (Sussams and
23 Leaton 2017). A rapid diffusion of household and commercial indoor heating and cooling based on
24 electricity could further reduce the demand for oil, coal and gas (Knobloch et al. 2019). Parallels can
25 be made with earlier literature on great waves of innovation, eras of clustered technological
26 innovation and diffusion between which periods of economic, financial and social instability have
27 emerged (Freeman and Louca 2001; Perez 2009).

28 Due to the predominantly international nature of fossil fuel markets, assets may be at risk from
29 regulatory and technological changes both domestically and in foreign countries (*medium*
30 *confidence*). Fossil-fuel exporting nations with lower competitiveness could lose substantial
31 amounts of industrial activity and employment in scenarios of peaking or declining demand for fossil
32 fuels. In scenarios of peaking oil demand, production is likely to concentrate towards the Middle-East
33 and OPEC countries (IEA 2017). Since state-owned fossil fuel companies tend to enjoy lower
34 production cost, privately-owned fossil fuel companies are more at risk (Thomä 2018). Losses of
35 employment may be directly linked to losses of fossil-related industrial activity or indirectly linked
36 through losses of large institutions, notably of government income from extraction royalties and export
37 duties. A multiplier effect may take place making losses of employment spill out of fossil fuel
38 extraction, transformation and transportation sectors into other supplying sectors (Mercure et al. 2018a).

39 **Main regulatory developments and voluntary responses to climate risk.** Framing climate risk as a
40 financial risk (not just as an ethical issue) is key for it to become an actionable criteria for investment
41 decision among mainstream investors (TCFD 2019) (*high confidence*). Since 2015 financial supervisors
42 and central banks (e.g. the Financial Stability Board, the G20 Green Finance Study Group, and the
43 Network for Greening the Financial System (NGFS)) have played a central role in raising awareness and
44 increase transparency of the potential material financial impacts of climate change within the
45 financial sector (Bank of England 2015, 2018; TCFD 2019). The NGFS initiative have engaged in
46 particular in the elaboration of climate financial risk scenarios, as mentioned earlier.

1 Although disclosure has increased since the TCFD recommendations were published, the information
2 is still insufficient for investors and more clarity is needed on potential financial impacts and how
3 resilient corporate strategies are under different scenarios (TCFD 2019). Several efforts to provide
4 guidance and tools for the application of the TCFD recommendations have been made (using SASB
5 Standards and the CDSB Framework to Enhance Climate-Related Financial Disclosures in Mainstream
6 Reporting TCFD Implementation Guide (UNEP FI 2018; CDSB and SASB 2019). Results of
7 voluntary reporting have been mixed, with one study pointing to unreliable and incomparable results
8 reported by the US utilities sector to the CDP (Stanny 2018).

9 There have been also similar initiatives at the national level (U.S. GCRP 2018; DNB 2017)(UK
10 Government 2017). In particular, France was the first country to mandate climate risk disclosure from
11 financial institutions (via Article 173 of the law on energy transition). However, disclosure responses
12 have been so far mixed in scope and detail, with the majority of insurance companies not reporting on
13 physical risk (Evain et al. 2018). In the UK, mandatory GHG emissions reporting for UK-listed
14 companies has not led to substantial emissions reductions to date but could be laying the foundation for
15 future mitigation (Tang and Demeritt 2018).

16 A key recent development is the EU Taxonomy for Sustainable Finance (TEG 2019), which provides a
17 classification of economic activities that (among other dimensions) contribute to climate mitigation or
18 can be enabling for the low-carbon transition. Indirectly, such classification provides useful information
19 on investors' exposure to transition risk (Alessi et al. 2019; ESMA 2020). Finally, many consultancies
20 have stepped forward offering services related to climate risk. However, the methods are typically
21 proprietary, non-transparent, or based primarily on carbon foot printing, which is a necessary but
22 insufficient measure of climate risk. Further, ESG (environmental, social and governance) metrics
23 can useful but are, alone, inadequate to assess climate risk.

24 **Illustrative mitigation pathways and financial risk for end-users of climate scenarios**

25 Decision makers in financial risk management make increasingly use of climate policy scenarios, in
26 line with the TCFD guidelines and the recommendations of the NGFS. In order to reduce the number
27 of scenarios to consider, Illustrative Mitigation Pathways (IMPs, Chapter 3), have been elaborated to
28 illustrate key features that characterise the possible climate (policy) futures. The following
29 considerations can be useful for scenario end-users who carry out risk analyses on the basis of the
30 scenarios described in Chapter 3. It is possible to associate climate policy scenarios with levels of
31 physical and/or transition risk, but these are not provided with the scenario data themselves.

32 On the one hand, each scenario is associated with a warming path, which in turn, on the basis of the
33 results from WGII, implies certain levels of physical risk (see WGII Chapter 16). However, climate
34 impacts are not accounted for in the scenarios. Moreover, levels of risk may vary with the Reason for
35 Concern (RFC, ibidem) and with the speed in the implementation of adaptation. On the other hand,
36 while mitigation can come with transition risk, in the case of lack of coordination among the actors, as
37 discussed earlier in this section, this is not modelled explicitly in the trajectories, since the financial
38 sector is not represented in underlying models. The scientific state of the art in climate-related financial
39 risk offers an analysis that is not yet comprehensive of both the physical and transition risk dimensions
40 in the same quantitative framework. However, decision makers can follow a mixed approach where
41 they can combine quantitative risk assessment for transition risk with more qualitative risk analysis
42 related to physical risk.

43 Figure 15.6 represents sequences of events following along a scenario both in terms of physical risk
44 (left) and transition risk (right). Four groups of IMPs (more are considered based on the warming level
45 they lead to in 2100. Current Policies (CurPol) considers climate policies implemented in 2020 with
46 only a gradual strengthening afterwards, leading to above 4°C warming (with respect to pre-industrial
47 levels). Moderate Action (ModAct) explores the impact of implementing the NDCs (pledged mitigation

1 targets) as formulated in 2020 and some further strengthening afterwards, leading to below 4°C, but
 2 above 3°C warming. In these two scenarios, there is no stabilization of temperature, meaning that further
 3 warming occurs after 2100 (and higher risk) even if stabilization could be eventually achieved. They
 4 are referred to as pathways with higher emissions. The warming levels reached along these two
 5 scenarios imply physical risk levels that are “Moderate” until 2050 and very high in 2050-2100 (with
 6 low levels of adaptation). Noting, that “Moderate” physical can mean for some countries (i.e. SIDS)
 7 significant and even hardly absorbable consequences (i.e. reaching hard adaptation limits). Transition
 8 risk is not relevant for these scenarios, since a transition is not pursued.

9 Illustrative Mitigation Pathways (IMP) include two groups of scenarios consistent with warming levels
 10 of 1.5°C and < 2°C, respectively. The two groups are representative for the IMPs defined in Chapter 3.
 11 In these scenarios, warming is stabilized before 2100. The warming levels along these paths imply
 12 “Moderate” physical risk until 2050 and “High” risk in 2050-2100 (with low levels of adaptation).
 13 Transition risk can arise along these trajectories from changes in expectations of economic actors about
 14 which of the scenarios is about to materialise. These changes imply, in turn, possible large variations in
 15 the financial valuation of securities and contracts, with losses on the portfolio of institutional investors
 16 and households. High policy credibility is key to avoid transition risk, by making expectations
 17 consistent early on with the scenario. Low credibility can delay the adjustment of expectations by
 18 several years, leading either to a late and sudden adjustment. However, if the policy never becomes
 19 credible, this changes the scenario since the initial target is not met.

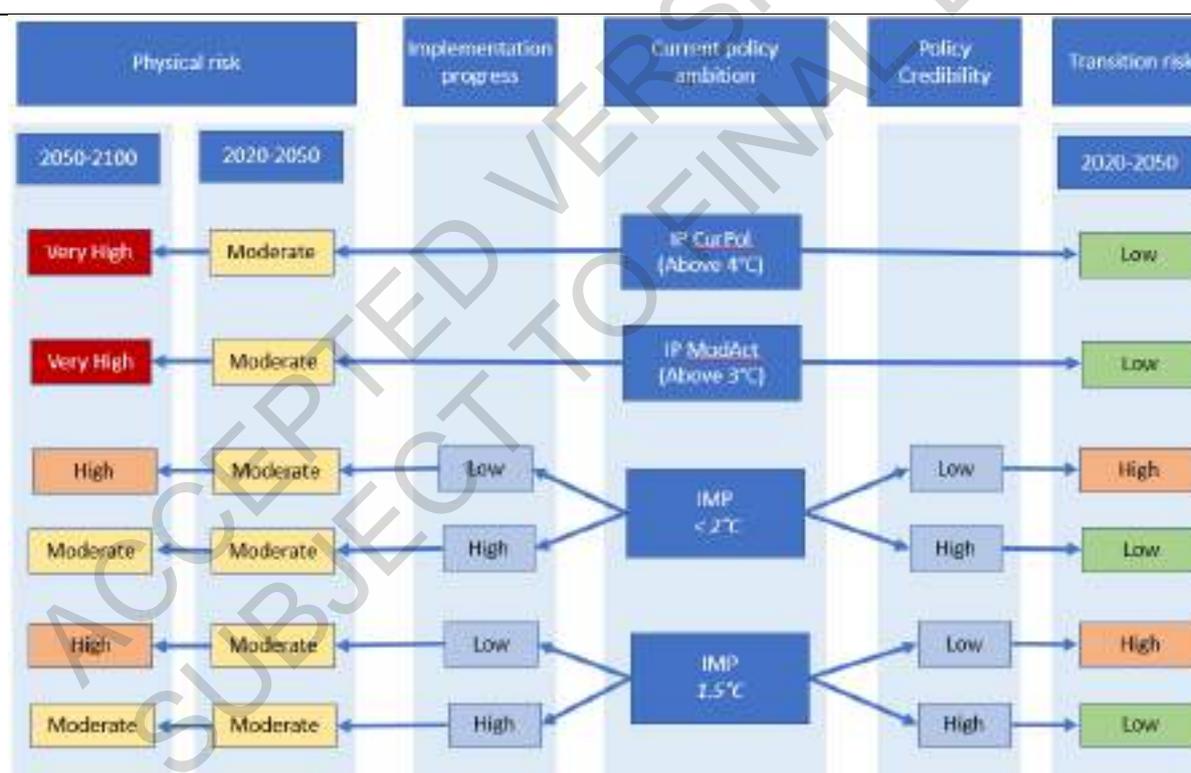

Figure 15.6 Schematic representation of climate scenarios in terms of both physical and transition risk.

While the figure does not cover all possible events, it maps out how the combination of stated targets can lead to different paths in terms of risk, depending on implementation progress and policy credibility. IMP 1.5°C and IMP < 2°C are representative for IMP-GS (Sens. Neg; Ren), IMP-Neg, IMP-LD; IMP-Ren; IMP-SP. Note that the figure defines "High" progress as higher, but it is important that the physical risk varies by region and country. This means, that “Moderate” physical risk can be significant and even hardly absorbable for some countries.

1 15.6.2 Enabling environments

2 The Paris Agreement recognised for the first time the key role of aligning financial flows to climate
3 goals. It further emphasises the importance of making financial flows to consistent with climate actions
4 and SDGs (Zamarioli et al. 2021). This alignment has now to be operated in a specific environment
5 where the scaling-up of climate policies is conditional upon their contribution to post-Covid recovery
6 packages (see 15.2.2, 15.2.3 and Box 15.6). The enabling environments are to be established account
7 for the structural parameters of the underinvestment on long-term assets. The persistent gap between
8 the ‘propensity to save’ and ‘propensity to invest’ (Summers 2016) obstructs the scaling up of climate
9 investments, and it results from a short-term bias of economic and financial decision making (Miles
10 1993; Bushee 2001; Black and Fraser 2002) that returns weighted on short-term risk dominate the
11 investment horizon of financial actors. Overcoming this bias is the objective of an enabling environment
12 apt to *launch of a self-reinforcing circle of trust* between project initiators, industry, institutional
13 investors, the banking system, and governments.

14 The role of government is crucial for creating an enabling environment for climate (Clark 2018), and
15 governments are critical in the launching and maintenance of this circle of trust by lowering the political,
16 regulatory risks, macroeconomic and business risks (*high confidence*). The issue is not just to
17 progressively enlarge the space of low-carbon investments but replacing one system (fossil fuels energy
18 system) rapidly by another (low-carbon energy system). This is a wave of ‘creative destruction’ with
19 the public support to developing new markets and new entrepreneurship and finance for green products
20 and technologies in a context which requires strong complementarities between Schumpeterian
21 (technological) and Keynesian (demand-related) policies (Dosi et al. 2017). However, it is challenging
22 to overcome the constraint of public budget under the pressure of competing demands and of
23 creditworthy constraints for countries that do not have an easy access to reserve currencies. It is needed
24 to maximize, both at the national and international levels, the leverage ratio of public funds engaged in
25 blended finance for climate change which is currently very low, especially in developing countries
26 (Attridge and Engen 2019).

27 **Transparency:** Policy de-risking measures, such as robust policy design and better transparency, as
28 well as financial de-risking measures, such as green bonds and guarantees, in both domestic and
29 international level, enhance the attractiveness of clean energy investments (Steckel and Jakob 2018)
30 (*high confidence*). Organizations such as the Task Force on Climate-related Financial Disclosures
31 (TCFD) can help increase capital markets’ climate financing, including private sector, by providing
32 financial markets with information to price climate-related risks and opportunities (TCFD 2020).
33 However, risk disclosures alone would likely be insufficient (Christophers 2017) (*high confidence*).
34 Transparency can help but on its own as long as market failures that inhibit the emergence of low-
35 carbon investment initiatives with positive risk-weighted returns (Ameli et al. 2020).

36 **Central banks and climate change.** Central banks in all economies will likely have to play a critical
37 role in supporting the financing of fiscal operations particularly in a post-COVID world (*high*
38 *confidence*). Instruments and institutional arrangements for better international monetary policy
39 coordination will likely be necessary in the context of growing external debt stress and negative credit
40 rating pressures facing both emerging and low-income countries. Central bankers have started
41 examining the implications of disruptive risks of climate change, as part of their core mandate of
42 managing the stability of the financial system (Chenet et al. 2021). Climate-related risk assessments
43 and disclosure, including central banks’ stress testing of climate change risks can be considered as a
44 first step (Rudebusch 2019), although such risk assessments and disclosure may not be enough by
45 themselves to spur increased institutional low-carbon climate finance (Ameli et al. 2020).

46 Green QE is now being examined as a tool for enabling climate investments (Dafermos et al. 2018) in
47 which central banks could explicitly conduct a program of purchases of low-carbon assets (Aglietta et
48 al. 2015). A green QE program ‘would have the benefit of providing large amounts of additional

1 liquidity to companies interested' in green projects (Campiglio et al. 2018) (*medium confidence*). Green
2 QE would have positive effects for stimulating a low-carbon transition, such as accelerating the
3 development of green bond markets (Hilmi et al. 2021), encouraging investments and banking reserves,
4 and reducing risks of stranded assets, while it might increase the income inequality and financial
5 instability (Monasterolo and Raberto 2017). While the short-term effectiveness would not be
6 substantial, the central bank's purchase of green bonds could have a positive effect on green investment
7 in the long run (Dafermos et al. 2018). However, the use of green QE needs to be cautious on potential
8 issues, such as undermining central bank's independence, affecting central bank's portfolio by including
9 green assets with poor financial risk standards, and potential regulatory capture and rent seeking
10 behaviours (Krogstrup and Oman 2019).

11 Additional monetary policies and macroprudential financial regulation may facilitate the expected role
12 of carbon pricing on boosting low-carbon investments (D'Orazio and Popoyan 2019) (*medium*
13 *confidence*). Commercial banks may not respond to the price signal and allocate credits to low-carbon
14 investments due to the existence of market failure (Campiglio 2016). This could support the
15 productivity of green capital goods and encourage green investments in the short-term, but might cause
16 financial instability by raising non-performing loans ratio of dirty investments and creating green
17 bubbles (Dunz et al. 2021). Financial supervisors needs to implement stricter guidelines to overcome
18 the greenwashing challenges (Caldecott 2020).

19 **Efficient Financial Markets and Financial Regulation.** An influential efficient financial markets
20 hypothesis (Fama 1970, 1991, 1997) proceeds from the assumption that in well-developed financial
21 markets, available information at any point of time is already well captured in capital markets with
22 many participants. Despite an increasing challenges to the theory (Sewell 2011), especially by repeated
23 episodes of global financial crashes and crises, and other widely noted anomalies, a weaker form of the
24 efficient markets hypothesis may still apply (*medium confidence*). It is arguable that accumulating
25 scientific evidence of climate impacts is being accompanied by rising levels of climate finance. Banks
26 and institutional investors are also progressively rebalancing their investment portfolios away from
27 fossil-fuels and towards low-carbon investments (IEA 2019b; Monasterolo and de Angelis 2020). In
28 the meantime, the world runs the risk of sharp adjustments, crises and irreversible 'tipping points'
29 (Lontzek et al. 2015) sufficiently destabilizing climate outcomes. This leads to the policy prescription
30 towards financial regulatory agencies requiring greater and swifter disclosure of information about
31 rising climate risks faced by financial institutions in projects and portfolios and central bank attention
32 to systemic climate risk problems as one possible route of policy action (Carney 2015; Dietz et al. 2016;
33 Zenghelis and Stern 2016; Campiglio et al. 2018). However, disclosure requirements of risks and
34 information in private settings remain mostly voluntary and difficult to implement (Battiston et al. 2017;
35 Monasterolo et al. 2017).

36 Nevertheless, financial markets are innovating in search of solutions (see 15.6.6). Recognizing and
37 dealing with stranded fossil-fuel assets is also a key area of growing concern that financial institutions
38 are beginning to grapple with. Larger institutions with more patient capital (pensions, insurance) are
39 also increasingly beginning to enter the financing of projects and green bond markets. The case for
40 efficient financial markets in developing countries is worse (Abbasi and Riaz 2016; Hong et al. 2019)
41 because of weaker financial institutions (Hamid et al. 2017), heightened credit rationing behaviour
42 (Bond et al. 2015), and high-risk aversion as most markets are rated as junk, or below/barely investment
43 grade (Hanusch et al. 2016). Other constraints such as limited long-term financial instruments and
44 underdeveloped domestic capital markets, absence of significant domestic bond markets for
45 investments other than sovereign borrowing, and inadequate term and tenor of financing, make the
46 efficient markets thesis practically inapplicable for most developing countries.

47 **Markets, finance and creative destruction.** Branches of macro-innovation theory could be grouped
48 into two principal classes (Mercure et al. 2016): 'equilibrium – optimisation' theories that treat

1 innovators as rational perfectly informed agents and reaching equilibrium under market price signals;
2 and the other ‘non-equilibrium’ theory where market choices are shaped by history and institutional
3 forces and the role of public policy is to intervene in processes, given a historical context, to promote a
4 better outcome or new economic trajectory. The latter suggests that new technologies might not find
5 their way to the market without price or regulatory policies to reduce uncertainty on expected economic
6 returns. A key issue is the perception of risk by investors and financial institutions. The financial system
7 is part of complex policy packages involving multiple instruments (cutting subsidies to fossil fuels,
8 supporting clean energy innovation and diffusion, levelling the institutional playing field and making
9 risks transparent) (Polzin 2017) and the needed big systemic push (Kern and Rogge 2016) requires it
10 takes on the role of ‘institutional innovation intermediaries’ (Polzin et al. 2016).

11 As far as climate finance is concerned, public R&D support had large cross-border knowledge spill-
12 overs indicating that openness to trade was important, capacity expansion had positive effects on
13 learning-by-doing on innovation over time, and that feed-in-tariffs (FiTs), in particular, had positive
14 impacts on technology diffusion (Grafström and Lindman 2017) (see box 16.4 for further findings of
15 public R&D on energy technologies). The FiTs program has been associated with rapid increase in early
16 renewables capacity expansion across the world by reducing market risks in financing and stability in
17 project revenues (Menanteau et al. 2003; Jacobsson et al. 2009). (see Chapter 9.9.5). Competitive
18 auctions that the successful bidder with the lowest price or other criteria is selected for government’s
19 call for tender are increasing being utilised as an alternative to FiTs due their strengths of flexibility,
20 potential for real price discovery, ability to ensure greater certainty in price and quantity and capability
21 to guarantee commitments and transparency (IRENA and CEM 2015).

22 Outside of RE, scattered but numerous examples are available on the role of innovative public policy
23 to spur and create new markets and technologies (Arent et al. 2017): i) pro-active role of the state in
24 energy transitions (the retirement of all coal-fired power plants in Ontario, Canada between 2007 and
25 2014 (Kern and Rogge 2016; Sovacool 2016), ii) Too early exit and design problems not considering
26 the market acceptability and financing issues (e.g., energy-efficient retrofitting in housing in UK
27 (Rosenow and Eyre 2016), low or negative returns in reality versus engineering estimates in
28 weatherisation programs in US (Fowlie et al. 2018)), iii) Energy performance contracting for sharing
29 the business risks and profits and improving energy efficiency (Energy service company (Bertoldi and
30 Boza-Kiss 2017; Qin et al. 2017) and Utility Energy Service Contracts in the US (Clark 2018)).

31 **Crowding out.** Literature has discussed the risks of a low effectiveness of public interventions and of
32 a crowding out effects of climate targeted public support to other innovation sectors (Buchner et al.
33 2013). However, much academic literature suggests no strong evidence of crowding out. (Deleidi et al.
34 2020). Examining the effect of public investment on private investment into renewables in 17 countries
35 over 2004-2014, showed that the concept of crowding out or in does not apply well to sectoral studies
36 and found that public investments positively support private investments in general.

37 **Support of climate action via carbon pricing, taxes, and emission trading systems.** Literature and
38 evidence suggest that futures markets regarding climate are incomplete because they do not price in
39 externalities (Scholtens 2017). As a result, low-carbon investments do not take place to socially and
40 economically optimal levels, and the correct market signals would involve setting carbon prices high
41 enough or equivalent trading in reduced carbon emissions by regulatory action to induce sufficient and
42 faster shift towards low-carbon investments (Aghion et al. 2016) (*high confidence*). Nonetheless,
43 durable carbon pricing in economic and political systems must be implemented and approached
44 combining related elements to both price and quantity (Grubb 2014).

45 The introduction of fiscal measures, such as carbon tax, or market-based pricing, such as emission
46 trading scheme, to reflect carbon pricing have benefits and drawbacks that policymakers need to
47 consider both country-specific conditions and policy characteristics. Carbon tax can be a simpler and
48 easier way to implement carbon pricing, especially in developing countries, because countries can

1 utilise the existing fiscal tools and do not need a concrete enabling conditions as market-based
2 frameworks (*high confidence*). The reallocation of revenues from carbon taxes can be used for low-
3 carbon investments, supporting poorer sections of society and fostering technological change (High-
4 Level Commission on Carbon Prices 2017). In combination with other policies, such as subsidies,
5 public R&Ds on resource-saving technologies, properly designed carbon taxes can facilitate the shift
6 towards low-carbon, resource-efficient investments (Bovari et al. 2018; Naqvi and Stockhammer 2018;
7 Dunz et al. 2021). (see Chapter 9.9.3 for carbon taxes). The effectiveness of carbon pricing has been
8 supported by various evidences. EU ETS has been cut the emissions by 42.8% in the main sectors
9 covered (European Commission 2021a), and China had achieved emissions reductions and energy
10 conservations through its pilot ETS between 2013 and 2015 (Hu et al. 2020; Zhang et al. 2019).
11 Institutional learning, administrative prudence, appropriate carbon revenue management and
12 stakeholder engagement are key ingredients for successful ETS regimes (Narassimhan et al. 2018).

13 The presence of carbon prices can promote low-carbon technologies and investments (Best and Burke
14 2018), and price signals, including carbon taxation, provide powerful and efficient incentives for
15 households and firms to reduce CO₂ emissions (IMF 2019). The expansion of carbon prices is dependent
16 on country-specific fiscal and social policies to hedge against regressive impacts on welfare,
17 competitiveness, and employment (Michaelowa et al. 2018). Such impacts need to be offset using the
18 proceeds of carbon taxes or auctioned emission allowances to reduce distortive taxation (Bovenberg
19 and de Mooij 1994; Goulder 1995; de Mooij 2000; Chiroleu-Assouline and Fodha 2014) and fund
20 compensating measures for the population sections that are most adversely impacted (Combet et al.
21 2010; Jaccard 2012; Klenert et al. 2018). This is more difficult for developing countries with a large
22 share of energy-intensive activities, fossil fuels exporting countries and countries which have lower
23 potential to mitigate impacts due to lower wages or existing taxes (Lefèvre et al. 2018).

24 Non-carbon price instruments, such as market-oriented regulation, public programs involving low
25 carbon infrastructure, may be preferential in developing countries where market and regulatory failure
26 and political economy constraints are more prevalent (Finon 2019). . While the carbon pricing was
27 suggested by many economists and researchers (Nordhaus 2015; Pahle et al. 2018), overcoming the
28 political and regulatory barriers would be necessary for the further implementation of an effective
29 carbon pricing nationally and internationally. Without the strong political support, the effectiveness of
30 carbon pricing would be limited to least-cost movements (Meckling et al. 2015).

31 **Role of domestic financing sources.** Efforts to address climate change can be scaled up through the
32 mobilisation of domestic funds (Fonta et al. 2018). Publicly organised and supported low-carbon
33 infrastructures through resurrected national development banks may be justified (Mazzucato and Penna
34 2016). It is important to efficiently allocate the public financing, and SIBs can take up key roles (i) to
35 provide capital to assist with overcoming financial barriers, (ii) to signal and direct investments towards
36 green projects, and (iii) to attract the private investors by taking up a de-risking role. Also, they can
37 become a first mover by investing in new and innovative technologies or business models (Geddes et
38 al. 2018). State owned enterprises (SOEs) can also have an overall positive effect on renewables
39 investments, outweighing any effect of crowding out private competitors (Prag et al. 2018). Green
40 investment banks (GIB) can assist in the green transition by developing valuable expertise in
41 implementing effective public interventions to overcome investment barriers and mobilise private
42 investment in infrastructure (OECD 2015c). De-risking measures may reduce investment risks, but
43 lacking research and data availability hinders designing such measures (Dietz et al. 2016). Local
44 governments efforts to de-risk by securitization might have negative effects by narrowing the scope for
45 a green developmental state and encouraging privatisation of public services (Gabor 2019).

46 **The potential role of coordinated multilateral initiatives.** There is a growing awareness of the low
47 leverage ratio of public to private capital in climate blended finance (Blended Finance Taskforce 2018b)
48 and of a glass ceiling', caused by a mix of agencies' inertia and perceived loss of control over the use

1 of funds, on the use of public guarantees by MDBs to increase it (Gropp et al. 2014; Schiff and Dithrich
2 2017; Lee et al. 2018) (*high confidence*). Many proposals have emerged for multilateral guarantee
3 funds: Green Infrastructure Funds (de Gouvello and Zelenko 2010; Studart and Gallagher 2015),
4 Multilateral Investment Guarantee Agency (Enhanced Green MIGA) (Déau and Touati 2018),
5 guarantee funds to bridge the infrastructure investment gap (Arezki et al. 2016), and multi-sovereign
6 guarantee mechanisms (Dasgupta et al. 2019). The obstacle of limited fiscal space for economic
7 recovery and climate actions in low-income and some emerging economies can be overcome only in a
8 multilateral setting. Several multilateral actions are being envisaged: G20's suspension of official
9 bilateral debt payments, IMF's adoption of new SDRs allocation (IMF 2021b). However, any form of
10 unconventional debt relief will generate development and climate benefits only if they credibly target
11 bridging the countries' infrastructure gap with low-carbon climate-resilient options.

12 An interest of multilateral setting is a credibility-enhancing effect provided by reciprocal gains for both
13 the donor and the host country. Guarantor countries can compensate the public cost of their commitments
14 with the fiscal revenues of induced exports. As to the host countries, they would benefit from new capital
15 inflows and the grant equivalents of reduced debt service which might potentially go far beyond 100
16 billion USD yr⁻¹ (Hourcade et al. 2021a). A second interest would be to support a learning process about
17 agreed-upon assessment and monitoring methods using clear metrics. Developing standardized and
18 science-based assessment methods at low transaction costs is essential to strengthen the credibility of
19 green investments and the emergence a pipeline of high-quality bankable projects which can be
20 capitalized in the form of credible assets and supported with transparent and credible domestic spending.
21 Multi-sovereign guarantees would provide a quality backing to developing countries and allow for
22 expanding developing countries' access to capital markets at a lower cost and longer maturities, overcome
23 the Basel III's liquidity impediment and the EU's Solvency II directive on liquidity (Blended Finance
24 Taskforce 2018b), accelerate the recognition of climate assets by investors seeking safe investments
25 havens (Hourcade et al. 2021b). It would also strengthen the efficacy of climate disclosure through high
26 grades climate assets and minimize the risks of 'greening' of the portfolios by investing in 'carbon neutral'
27 activities and not in low carbon infrastructures. Finally, it would free up grant capacities for SDGs and
28 adaptation that mostly involve non-marketable activities by crowding in private investments for
29 marketable mitigation activities.

30 *** START BOX 15.5 ****

31 **Box 15.5 The role of enabling environments for decreasing-economic cost of renewable energy**

32 A widely used indicator for the relative attractiveness of renewable energy but also development of
33 price levels is the levelized cost of energy (LCOE). It is applied by a wide range of public and private
34 stakeholders when tracking progress with regard to cost degression (Aldersey-Williams and Rubert
35 2019). LCOE calculation methodologies vary but in principle, consider project-level costs only (NEA
36 1989). Besides other weaknesses, the LCOE concept usually does not consider societal costs resulting
37 from de-risking instruments and/or other public interventions/support and therefore caution has to be
38 applied when using the LCOE as the indicator sole of the success of enabling environments. The yearly
39 IRENA mapping on renewable energy auction results demonstrates the extremely broad ranges of
40 LCOEs (equal to the agreed tariffs) for renewable energy which can be observed (IRENA 2019a). For
41 example, in 2018, solar PV LCOEs for utility-scale projects came in between 0.04 USD/kWh and 0.35
42 USD/kWh with a global weighted average of 0.085 USD/kWh. However, comparative analysis taking
43 into account societal costs are hardly available driven by challenges in the context of the quantification
44 of public support.

45 The GET FiT concept argued that the mitigation of political and regulatory risk by sovereign and
46 international guarantees is cost-efficient in developing countries illustrating the estimated impact of
47 such risk-mitigation instruments on equity and debt financing costs and consequently required feed-in
48 tariff levels (Deutsche Bank Climate Change Advisors 2011). The impact of financing costs on cost of

1 renewable energy generation is well researched with significant differences across countries and
2 technologies being observed with major drivers being the regulatory framework as well as the
3 availability and type of public support instruments (Geddes et al. 2018; Steffen 2019). With a focus on
4 developing countries and based on a case study in Thailand, (Huenteler et al. 2016) demonstrate the
5 significant effect of regulatory environments but also local learning and skilled workforce on cost of
6 renewables. The effect of those exceeds the one of global technology learning curves.

7 (Egli et al. 2018) identify macroeconomic conditions (general interest rate) and experience effects
8 within the renewable energy finance industry as key drivers in developed countries with a stable
9 regulatory environment contributing 5% (PV) and 24% (wind) to the observed reductions in LCOEs in
10 the German market with a relatively stable regulatory environment. They conclude that ‘extant studies
11 may overestimate technological learning and that increases in the general interest rate may increase
12 renewable energies’ LCOEs, casting doubt on the efficacy of plans to phase out policy support’ (Egli et
13 al. 2018). A rising general interest rate level could heavily impact LCOEs – for Germany, a rise of
14 interest rates to pre-financial crisis levels in five years could increase LCOEs of solar and wind by 11–
15 25% respectively (Schmidt et al. 2019).

16 *** END BOX 15.5 ****

17 ***15.6.2.1 The public-private and mobilization narrative and current initiatives***

18 Financing by development finance institutions and development banks aims to address market failures
19 and barriers related to limited access to capital as well as provides direct and indirect subsidisation by
20 accepting higher risk, longer loan tenors and/or lower pricing. Many development and climate projects
21 in developing and emerging countries have traditionally been supported with concessional loans by
22 DFIs/IFIs. With an increasing number of sectors becoming viable and increasing complaints of private
23 sector players with regard to crowding-out (Bahal et al. 2018), a stronger separation and crowding-in
24 of commercial financing at the project/asset level is targeted. MDBs and IFIs were crucial for opening
25 and growth in the early years of the green bonds, which represent a substantial share of issuances (CBI
26 2019a). Drivers of an efficient private sector involvement are stronger incentives to have projects
27 delivered on time and in budget as well as market competition (Hodge et al. 2018). It remains key that
28 the private sector mobilization goes hand in hand with institutional capacity building as well as strong
29 sectoral development in the host country as a strong, knowledgeable public partner with the ability to
30 manage the private sector is a dominating success factor for public-private cooperation (WEF 2013;
31 Yescombe 2017; Hodge et al. 2018).

32 Limited research is available on the efficiency of mobilization of the private sector at the various levels
33 and/or the theory of change attached to the different approaches as applied in classical PPP. Also,
34 transparency on current flows and private involvement at the various levels is limited with no
35 differentiation being made in reporting (e.g., GCF co-financing reporting). Limited prioritization and
36 agreement on prioritization on sectors and/or project categories being ready and/or preferred for direct
37 private sector involvement which might become a challenge in the coming years (Sudmant et al.
38 2017a,b) (*high confidence*).

39 Public guarantees have been increasingly proposed to expand climate finance, especially from the
40 private sector, with scarce public finance, by reducing the risk premium of the low-carbon investment
41 opportunities (de Gouvello and Zelenko 2010; Emin et al. 2014; Studart and Gallagher 2015; Schiff and
42 Dithrich 2017; Lee et al. 2018; Steckel and Jakob 2018). They have the advantage of a broad coverage
43 including the 'macro' country risks and to tackle the up-front risks, during the preparation, bidding and
44 development phases of the project life cycle that deter projects initiators especially for capital intensive
45 and immature options. Insurances are also powerful de-risking instruments (Déau and Touati 2018) but
46 they entitle the issuer to review claims concerning events and cannot cope with up-front costs.
47 Contractual arrangements like power purchase agreements are powerful instruments to reduce market
48 risks through a guaranteed price but they weigh on public budgets. Risk-sharing that bring together

1 public agencies, firms, local authorities, private corporates, professional cooperatives, and institutional
2 financiers can reduce costs (UNEP 2011), and support the deployment of innovative business models
3 (Déau and Touati 2018). Combined with emission taxes they can contribute to reducing credit rationing
4 of immature and risky low-carbon technologies (Haas and Kempa 2020).

5

6 **15.6.3 Considerations on availability and effectiveness of public sector funding**

7 The gap analysis as well as other considerations presented in this chapter illustrate the critical role of
8 increased volumes and efficient allocation of public finance to reach the long-term global goals, both
9 nationally and internationally.

10 **Higher public spending levels driven by the impacts of COVID-19 and related recovery packages.**

11 Higher levels of public funding represent a massive chance but also a substantial risk. A missing
12 alignment of public funding and investment activity with the Paris Agreement (and sustainable
13 development goals) would result in significant carbon lock-ins, stranded assets and thus increase
14 transition risks and ultimately economic costs of the transition (*high confidence*). Using IMF data for
15 stimulus packages, (Andrijevic et al. 2020) estimated that COVID-19 related fiscal expenditure had
16 surpassed 12 trillion USD by October 2020 (80% in OECD countries), a third of which being spent in
17 liquidity support and healthcare. Total stimulus pledged to date are ten times higher than low-Paris-
18 consistent carbon investment needs from 2020–2024 (Andrijevic et al. 2020; Vivid Economics 2020).
19 Overall, stimulus packages launched include 3.5 trillion USD to sectors directly affecting future
20 emissions, with overall fossil-fuel investment flows outweighing low-carbon technology investment
21 (Vivid Economics 2020).

22 Lessons from the global financial crises show that although deep economic crises create a sharp short-
23 term emission drop, and green stimulus is argued to be the ideal response to tackle both the economic
24 and the climate crises at once, disparities between regional strategies hinder the low carbon transition
25 (*high confidence*). Indeed, inconsistent policies within countries can also counterbalance emission
26 reductions from green stimulus, as well as a lack of transparency and green spending pledged not
27 materialised (Jaeger et al. 2020). Also, aggressive monetary policy as a response to the global financial
28 crisis, including quantitative easing that did not target low-carbon sectors, has been heavily criticised
29 (Jaeger et al. 2020). The COVID-19 crisis recovery, in contrast, benefits from developments which
30 have taken place since, such as an emerging climate-risk awareness from the financial sector, reflected
31 in the call from the Coalition of Finance Ministers for Climate Action (Coalition of Finance Ministers
32 for Climate Action 2020), which reunites 50 countries' finance ministers, for a climate-resilient
33 recovery.

34 The steep decrease in renewable electricity costs since 2010 also represents a relevant driver for a low
35 carbon recovery (Jaeger et al. 2020). Many more sectors are starting to show similar opportunities for
36 rapid growth with supportive public spending such as low-carbon transport and buildings (IEA 2020d).
37 Expectations that the package will increase economic activity rely on the assumption that increased
38 credit will have a positive effect on demand, the so-called demand-led policy (Mercure et al. 2019).
39 Boosting investment should propel job creation, increasing household income and therefore demand
40 across economic sectors (*high confidence*). A similar plan has also been proposed by the US
41 administration and the European Union through the Next Generation EU (European Council 2020).

42 Nevertheless, three uncertainties remain. First, only those countries and regions with highest credit-
43 ratings (AAA or AA) with access to deep financial markets and excess savings will be able to mount
44 such counter-cyclical climate investment paths, typically high-income developed economies (*high*
45 *confidence*). In more debt constrained developing countries have and lower access to global savings
46 pool countries because of higher risk perceptions and lower credit ratings (BBB or less), exacerbated
47 by COVID-19 and already leading to credit downgrades and defaults (Kose et al. 2020) and have long

1 tended to be fiscally pro-cyclical (Mcmanus and Ozkan 2015). These include the general class of
2 virtually all major emerging and especially low-income developing countries, to which such demand-
3 stimulating counter-cyclical climate consistent borrowing path is likely To access such funds, these
4 countries would need globally coordinated fiscal policy and explicit supporting cross-border
5 instruments, such as sovereign guarantees, strengthening local capital markets and boosting the 100
6 billion USD annual climate finance commitment (Dasgupta et al. 2019).

7 Second, a strong assumption is that voters will be politically supportive of extended and increased fiscal
8 deficit spending on climate on top of COVID-19 related emergency spending and governments will
9 overcome treasury biases towards fiscal conservatism (to preserve credit ratings). However, evidence
10 strongly suggests that voters (and credit rating agencies) tend to be fiscally conservative (Peltzman
11 1992; Lowry et al. 1998; Alesina et al. 2011; Borge and Hopland 2020) especially where expenditures
12 involve higher taxes in the future and do not identifiably flow back to their local bases (the ‘public
13 good’ problem) (*high confidence*). Such mistrust has been a reason for abortive return to fiscal austerity
14 often in the past (most recently during global financial crisis) and may benefit for political support by
15 consistently reframing the climate expenditures in terms of job creation benefits (Bougrine 2012),
16 effectiveness of least-cost fiscal spending on climate for reviving private activity, and the avoidance of
17 catastrophic losses (Huebscher et, al. 2020) from higher carbon emissions. A new understanding of debt
18 sustainability including negative implications of deferred climate investments on future GDP has not
19 yet been mainstreamed (see more on the debt sustainability discussion below (e.g. (Buhr et al. 2018;
20 Fresno 2020)). In addition, implications on the availability of international public finance flows are
21 not yet clear since current additional funding prioritises urgent healthcare support rather than an increase
22 of predictable mid/long-term financial support. Heavy investment needs for recovery packages in
23 developed countries on the one hand and their international climate finance commitments might be
24 perceived to compete for available “perceived as appropriate” budgets.

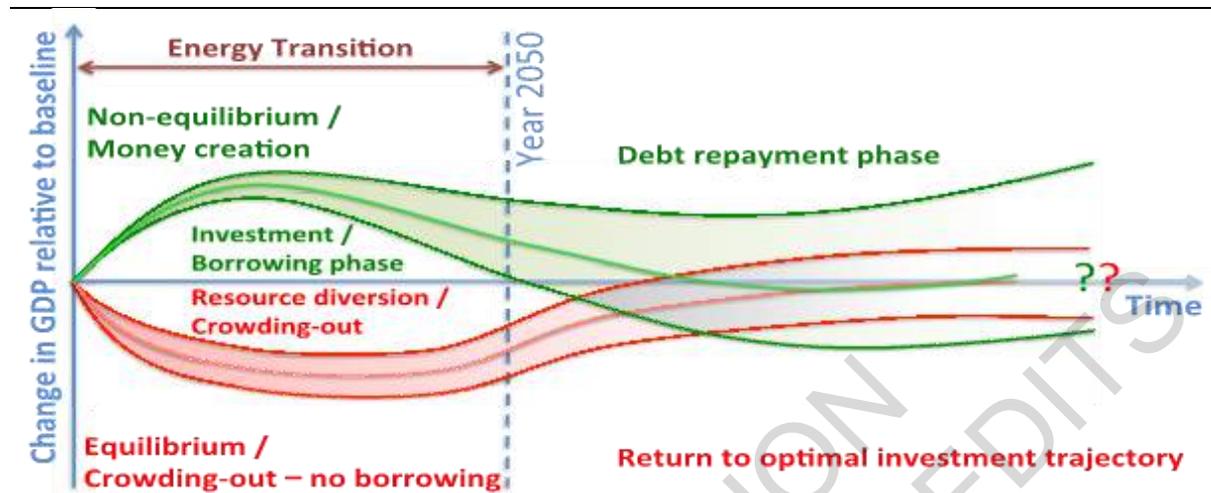

25 *** START BOX 15.6 ****

26 **Box 15.6 Macroeconomics and finance of a Post-COVID-19 green stimulus economic recovery**
27 **path**

28 Financial history suggests that capital markets may be willing to accommodate extended public
29 borrowing for transient spending spikes (Barro 1987) when macroeconomic conditions suggest excess
30 savings relative to private investment opportunities (Summers 2015) and when public spending is seen
31 as timely, effective and productive, with governments able to repay when conditions improve as
32 economic crisis conditions abate (*high confidence*). A surge in global climate mitigation spending in
33 the post-pandemic recovery may be an important opportunity, which global capital markets are
34 signalling (Global Investor Statement 2019). The standard ‘neo-classical’ macroeconomic model is
35 often used in integrated energy-economy-climate assessments (Balint et al. 2016; Nordhaus 2018). This
36 class of Computable General Equilibrium (CGE) models, however, have a limited treatment of the
37 financial sector and assume that all resources and factors of production are fully employed, there is no
38 idle capacity and no inter-temporal financial intermediation (Pollitt and Mercure 2018b). Investment
39 cannot assume larger values than the sum of previously determined savings, as a fixed proportion of
40 income. Such constraint, as stressed by (Mercure et al. 2019), implies that investment in low-carbon
41 infrastructure, under the equilibrium assumptions, necessarily creates a (neo-Ricardian) crowding-out
42 effect that contracts the remaining sectors. The graphic below shows the implications (in the red-shaded
43 part of Figure 1).

44 Post-Keynesian demand-side macroeconomic models, with financial sectors and supply-side effects, in
45 contrast, allow for the reality of non-equilibrium situations: persistent short to medium term
46 underemployed economy-wide resources and excess savings over investment because of unexpected
47 shocks, such as COVID-19. In these settings, economic stimulus packages allow a faster recovery with

1 demand-led effects: “Economic multipliers are near zero when the economy operates near capacity. In
 2 contrast, during crises such as the GFC, economic multipliers can be high (Blanchard and Leigh 2013;
 3 Hepburn et al. 2020b). The expected results are opposite to the standard supply-led equilibrium models
 4 as a response to investment stimulus (the green-shaded part of Box 15.6, Figure 1), as intended by
 5 ‘green-stimulus’ packages such as proposed by the EU (Balint et al. 2016; Mercure et al. 2019).

Box 15.6, Figure 1 Two Worlds – Energy transition outcomes under alternative model assumptions (Keynesian vs General Equilibrium) Source: Mercure et al. (2019)

6 Even if demand-led models work better in depressions, the question nevertheless is whether the
 7 additional public borrowing for such ‘green stimulus’ can be undertaken by market borrowings given
 8 already high public debt levels and recovered in the future from taxes as the economy revives. The
 9 results of recent macroeconomic modelling work (Liu et al. 2021) represented by 10 major
 10 countries/regions suggests answers. It uses a non-standard macroeconomic framework, with Keynesian
 11 features such as financial and labour market rigidities and fiscal and monetary rules (McKibbin and
 12 Wilcoxon 2013). First, a global ‘green stimulus’ of about an average of 0.8% of GDP annually in
 13 additional fiscal spending between 2020-30 would be required to accelerate the emissions reduction
 14 path required for a 1.5°C transition. Second, such a stimulus would also accelerate the global recovery
 15 by boosting GDP growth rates by about 0.6% annually during the critical post-COVID period. Third,
 16 the optimal tax policy would be to backload the carbon taxes to later in the macroeconomic cycle, both
 17 because this would avoid dampening near-term growth while pre-announced carbon tax plans would
 18 incentivise long-term private energy transition investment decisions today and provide neutral
 19 borrowing. This macroeconomic modelling path thus replicates the ‘green stimulus’ impacts expected
 20 in theory (Box 15.6, Figure 1). There are also some other additional features of the modelled proposal:
 21 (a) fiscal stimulus—needed in the aftermath of the pandemic—can be an opportunity to boost green and
 22 resilient public infrastructure; (b) green research and development ‘subsidies’ are feasible to boost
 23 technological innovations; and (c) income transfers to lower income groups are necessary to offset
 24 negative impacts of rising carbon taxes.

25 Substantial effects of the COVID-19 pandemic, which is relatively unique on its public health impacts
 26 when combined with the consequences of deep economy-wide shocks (economic downturn, public
 27 finances, and debt), are expected to last for decades even in the absence of no significant future
 28 recurrence. A scenario where the pandemic recurs mildly every year for the foreseeable future further
 29 hinders GDP and investment recovery, where growth is unlikely to rebound to previous trajectories,
 30 even within OECD economies (McKibbin and Vines 2020) and with worse effects in developing
 31 regions. History is strongly supportive: studies on the longevity of pandemics’ impacts indicate
 32 significant macroeconomic effects persisting for decades, with depressed real rates of return, increased
 33 precautionary savings (Jordà et al. 2020), unemployment (Rodríguez-Caballero and Vera-Valdés 2020)

1 and social unrest (Barrett and Chen 2021). The direct effect on emissions is likely to be a small reduction
2 from previous trajectories, but the longer-lasting impacts are more on the macroeconomic-finance side.
3 Pandemic responses have increased sovereign debt across countries in all income bands (IMF 2021e).
4 However, its sharp increase in most developing economies and regions has caused debt distress (Bulow
5 et al. 2021), widening the gap in developing countries' access to capital (Hourcade et al. 2021b). While
6 strong coordinated international recovery strategies with climate-compatible economic stimulus is
7 justified (Pollitt et al. 2021; Barbier 2020; Barbier and Burgess 2020; Le Quéré et al. 2021; IMF 2020c),
8 national recovery packages announced do not show substantial alignment with climate goals (Shan et
9 al. 2021; Rochedo et al. 2021; D'Orazio 2021; Hourcade et al. 2021b). Contradictory post-COVID-19
10 investments in fossil fuel-based infrastructure may create new carbon lock-ins, which would either
11 hinder climate targets or create stranded assets (Hepburn et al. 2020a; Le Quéré et al. 2021; Shan et al.
12 2021), whilst deepening global inequalities (Hourcade et al. 2021b).

13

*** END BOX 15.6 ***

14 **Considerations on global debt levels and debt sustainability as well as implications for climate**
15 **finance.** The Paris Agreement marked the consensus of the international community that a temperature
16 increase of well below 2 degrees needs to be achieved and the SR1.5 has demonstrated the economic
17 viability of 1.5°C. However, in terms of increase of supply of, in particular, public finance, often the
18 debate is still driven by the question on affordability, considerations around financial debt sustainability
19 and budgetary constraints against the background of macroeconomic headwinds – even more in the
20 (post-)COVID-19 world (*high confidence*). The level of climate alignment of debt is hardly considered
21 in debt related regulation and/or debt sustainability agreements like the Maastricht Treaty ceilings (3%
22 of GDP government deficit and 60% of GDP (gross) government debt) not considering economic costs
23 of deferred climate action as well as economic benefits of the transformation.

24 Robust studies on the economic costs and benefits in the short- to long-term of reaching the LTGG exist
25 for only few countries and/or regions, primarily in the developed world (e.g. (BCG 2018; McKinsey
26 2020a) (*high confidence*). With many studies underpinning the strong economic rationale for high
27 investments in the short-term e.g.(McKinsey 2020a) [More studies to be added], regional differences
28 are significant highlighting the need for extensive cooperation and solidarity initiatives.

29 For many developing countries, the focus of debt sustainability discussions is on the negative effect of
30 climate change on the future GDP and the uncertainty with regard to short-term effects of climate
31 change and their economic implications (*high confidence*). With long-term economic impacts of climate
32 change being in the focus of the modelling community, the volatility of GDP in the short term driven
33 by shocks is more difficult to analyse and requires country-specific deep-dives. IPCC scenario data is
34 often not sufficient to perform such analysis with additional assumptions being needed (Acevedo 2016)
35 [Check for cross-referencing to WG1]. For debt sustainability analysis, these more short-term impacts
36 are, however, a crucial driver with transparency being limited to the significance of climate-related
37 revision of estimates. The latter might result in a continued overestimation of future GDP as happened
38 in the past increasing the vulnerability of highly indebted countries (Guzman 2016; Mallucci 2020).
39 While climate change considerations have already impacted country ratings and debt sustainability
40 assessments (and financing costs), it is unclear whether current GDP forecasts are realistic. The review
41 of the IMF debt sustainability framework leads to a stronger focus on vulnerability rather than only
42 income thresholds when deciding upon eligibility for debt relief and/or concessional resources (Mitchell
43 2015), which could become a mitigation factor for the challenge described before.

44 Debt levels globally but particularly in developing and vulnerable countries have significantly increased
45 over the past years with current and expected climate change impacts further burdening debt
46 sustainability (*high confidence*). For low and middle income countries, 2018 marked a new peak of debt
47 levels amounting to 51% of GDP; between 2010 and 2018, external debt payments as a percentage of

1 government budget grew by 83% in low- and middle-income countries, from an average of 6.71% in
2 2010 to an average of 12.56% in 2018 (Eurodad 2020). COVID-19 has further reduced the fiscal space
3 of many developing governments and/or increased the likelihood of debt stress. With many vulnerable
4 countries already being burdened with higher financing costs, this limited fiscal space further shrinks
5 their ability to actively steer the required transformation (Buhr et al. 2018). Limited progress in
6 increasing debt transparency remains another burden (see Section 15.6.7).

7 Considering the need for responses to both, short-term liquidity issues and long-term fiscal space,
8 current G20/IMF/World Bank debt service suspension initiatives are focused the liquidity issue rather
9 than underlying problems of more structural nature of many low-income (Fresnillo 2020). In order to
10 ensure fiscal space for climate action in the coming decade a mix between debt relief, deferrals of
11 liabilities, extended debt levels and sustainable lending practices including new solidarity structures
12 need to be considered in addition to higher levels of bilateral and multilateral lending to reduce
13 dependency on capital markets and to bridge the availability of sustainably structured loans for highly
14 vulnerable and indebted countries. More standardised debt-for-climate swaps, a higher share of GDP
15 linked bonds or structures ensuring (partial) debt cancellation in case countries are hit by physical
16 climate change impacts/shocks appear possible. The “hurricane” clause introduced by Grenada, or
17 wider natural disaster clauses provide issuers with an option to defer payments of interest and principal
18 in the event of a qualifying natural disaster and can reduce short-term debt stress (UN AAAA Art. 102)
19 (UN 2015a). A mainstreaming of such clauses has been pushed by various international institutions.
20 The collective action clause might be a good example of a loan/debt term which became market
21 standard. Definition of triggers is likely the most complex challenge in this context.

22 The use of debt-for-nature and debt-for-climate-swaps is still very limited and not mainstreamed but
23 offers significant potential if used correctly (*high confidence*).

24 An increasing number of debt-for-climate/nature swaps have been seen in recent years applied primarily
25 in international climate cooperation and in bilateral contexts, however, not (yet) to an extent addressing
26 severe and acute debt crises (Essers et al. 2021; Volz et al. 2021) offering significant potential if used
27 correctly (Warland and Michaelowa 2015). Significant lead times, needs-based structuring,
28 transparency with regard to the additionality of financed climate action, uncertainty with regard to own
29 resource constraints and ODA accountability remain as barrier for a massive scale-up needed to make
30 transactions relevant (Mitchell 2015; Fuller et al. 2018; Essers et al. 2021). At the same time, the
31 limitation of the use of debt-based instruments as a response to climate-related disasters and counter-
32 cyclical loans might be necessary (Griffith-Jones and Tyson 2010).

33 Ensuring efficient debt restructuring and debt relief in events of extreme shocks and imminent over-
34 indebtedness and sovereign debt default are further crucial elements with a joint responsibility of
35 debtors and creditors (UN 2015a) 2015). In this context, the Commonwealth Secretariat flagged that
36 the diversification of the lender portfolio made debt restructuring more difficult with more and more
37 heterogeneous stakeholders being involved (Mitchell 2015) and the UN AAAA raising concerns about
38 non-cooperative creditors and disruption of timely completion of debt restructuring (UN 2015a) 2015).
39 This is a side effect of a stronger use of capital markets, which need to be carefully considered in the
40 context of sovereign bond issuances (see also 15.6.7).

41 **Stranded assets.** The debate around stranded assets focuses strongly on the loss of value to financial
42 assets for investors (see Section 15.6.1, para. on the assessment of transition risk and carbon stranded
43 assets), however, stranded asset and resources in the context of the transition towards a low emission
44 economy “are expected to become a major economic burden for states and hence the tax payers” (EEAC
45 2016) (*high confidence*). Assets include not only financial assets but also infrastructure, equipment,
46 contracts, know-how, jobs as well as stranded resources (Bos and Gupta 2019). Besides financial
47 investors and fiscal budgets, consumers remain vulnerable to stranded investments. Against the
48 background of the frequent simultaneousness of losses occurring for financial investors on the one hand

1 and negative employment effects as well as regional development and fiscal effects, negotiations about
2 compensations and public support to compensate for negative effects of phasing out of polluting
3 technologies often remain interlinked and compensation mechanisms and related redistribution effects
4 untransparent.

5 Recent phase-out deals tend to aim for a (partial or full) compensation rather than no relief for losses.
6 In contrast to the line of argument in the tobacco industry, the backward looking approach and a
7 resulting obligation of compensation by investors in polluting assets can be observed rarely with the
8 forward looking approach of compensations by future winners for current losers dominating – despite
9 the high level of awareness about carbon externalities and resulting climate change impacts among
10 polluters for many years (van der Ploeg and Rezai 2020). In particular, transactions in the energy sector
11 show a high level of investor protection also against much needed climate action which is also well
12 illustrated by share of claims settled in favour of foreign investors under the Energy Charter Treaty and
13 investor-state dispute settlement (Bos and Gupta 2019).

14 Late government action can delay action and consequently strengthen the magnitude of action needed
15 at a later point in time with implications on employment and economic development in impacted regions
16 requiring higher level of fiscal burden (*high confidence*). This has also be considered in the context of
17 global climate cooperation with prolonged support for polluting infrastructure resulting heavy lock-in
18 effects and higher economic costs in the long-run (Bos and Gupta 2019). Despite a significant share of
19 fossil resources which need to become stranded in developing countries to reach the LTGG, REDD+
20 remains a singular example for international financial cooperation in the context of compensation for
21 stranded resources. [Potentially add sentence on ADB buyout facility]

22

23 **15.6.4 Climate-risk pooling and insurance approaches**

24 Since 2000, the world has been experiencing significant increase in economic losses and damages from
25 natural disasters and weather perils such as tropical cyclones, earthquake, flooding and drought. Total
26 global estimate of damage is about 4,210 billion USD, 2000-2018 (Aon Benfield UCL Hazard Research
27 Centre 2019). The largest portion of this is attributed to tropical cyclones (1,253 billion USD), followed
28 by flooding (914 billion USD), earthquakes (757 billion USD) and drought (approximately 372 billion
29 USD, or about 20 billion USD yr⁻¹ losses) (Aon Benfield UCL Hazard Research Centre 2019). In the
30 period 2017–2018, natural catastrophe losses total approximately 219 billion USD (Bevere 2019).
31 According to the National Oceanic and Atmospheric Administration, 14 weather and climate disasters
32 cost 91 billion USD in 2018 (NOAA NCEI 2019). The European Environment Agency reports that
33 ‘disasters caused by weather and climate-related extremes accounted for some 83% of the monetary
34 losses over the period 1980–2017 for EU Member States (EU-28) and that weather and climate-related
35 losses amounted to 426 billion EUR. For the EEA member countries (EEA-33), the ‘total reported
36 economic losses caused by weather and climate-related extremes’ over the same period amounted to
37 approximately 453 billion EUR (EEA 2019), (EEA 2019). Asia Pacific and Oceania has been
38 particularly impacted by typhoon and flooding (China, India, the Philippines) resulting in economic
39 losses of 58 billion USD, 2000–2017, and combination of flooding typhoon and drought totalling 89
40 billion USD in 2018 (inclusive of loss by private insurers and government sponsored programs (Aon
41 Benfield UCL Hazard Research Centre 2019). Based on past historical analysis, a region such as the
42 Caribbean, which has experienced climate-related losses equal to 1% of GDP each year since 1960 is
43 expected to have significant increases in such losses in the future leading to possible upwards of 8% of
44 projected GDP in 2080 (Commonwealth Secretariat 2016). Similarly, Latin America countries, such as
45 Argentina, El Salvador and Guatemala, experienced severe losses in agriculture totalling about 6 billion
46 USD due to drought in 2018 (Aon Benfield UCL Hazard Research Centre 2019). In the African region,
47 where climate change is projected to get significantly warmer, continuing severe drought in parts of
48 East Africa Tropical and Cyclone Idai, had devastating economic impacts. Mozambique, Zimbabwe

1 and Malawi (WMO 2019). According to Munich Re, loss from about 100 significant events in 2018 for
2 Africa are estimated at 1.4 billion USD (Munich Re 2019).

3 While there are questions about the sufficiency of insurance products to address the losses and damages
4 of climate-related disasters, insurance can help to cover immediate needs directly, provide rapid
5 response and transfer financial risk in times of extreme crisis (GIZ 2015; Lucas 2015; Schoenmaker
6 and Zachmann 2015; Hermann et al. 2016; Wolfrom and Yokoi-Arai 2016; Kreft and Schäfer 2017;
7 UNESCAP 2017; Matias et al. 2018; UNECA 2018; Broberg and Hovani-Bue 2019; EEA 2019;
8 Martinez-diaz et al. 2019) (*high confidence*). Commercial insurability is heavily driven by the
9 predictability of losses and the resulting ability to calculate insurance premium levels properly. Climate
10 change has become a major factor of increasing uncertainty. The previously strong reliance on historic
11 data in calculation of premium levels may be but a starting point given the likely need for upward
12 adjustment due to climate change and potential consequential economic damage. Different risk
13 perceptions between policyholders and insurers will create contrary assessments on premium levels and
14 consequently underinsurance. (McKinsey 2020b) also stresses the systemic effect of climate change on
15 insurers' business models and resulting availability of appropriate insurance products.

16 The conventional approach to such protective or hedging position has been indemnity and other
17 classical insurance micro, meso and macro level schemes (Hermann et al. 2016). These include micro
18 insurance schemes such as index insurance and weather derivative approaches that cover individual's
19 specific needs such as coverage for farm crops. Meso level insurance schemes, which primarily benefit
20 intermediary institutions, such as NGOs, credit union, financial institutions and farmer credit entities,
21 seek to reduce losses caused by credit default thereby 'enhancing investment potential', whereas macro-
22 level insurance schemes 'allow both insured and uninsured individuals to be compensated for damages
23 caused by extreme weather events' (Hermann et al. 2016). These macro-level insurance include
24 catastrophe bonds and weather derivatives etc. that transfer risk to capital market (Hermann et al. 2016).
25 Over the last decades, there have been a trend towards weather-index insurance and other parametric
26 insurance products based on predefined pay-out risk pooling instrument. It has gained favour with
27 governments in developing regions such as Africa, the Caribbean and the Pacific because it provides
28 certainty and predictability about funding - financial preparedness - for emergency actions and initial
29 reconstruction and reduces moral hazard. This 'financial resilience' is also increasingly appealing to the
30 business sector, particularly MSMEs, in developing countries (MEFIN Network and GI RFPI Asia
31 2016; Woods 2016; Schaer and Kuruppu 2018).

32 To date, sovereign parametric climate risk pooling as a way of managing climate risk does not seem to
33 have much traction in developed countries and does not appear to be attractive to actors in the G-20
34 countries. No G-20 members are yet party to any climate risk pooling initiative (Kreft and Schäfer
35 2017). However, international bilateral donors such as the USAID and the Foreign, Commonwealth &
36 Development Office (FCDO, formerly DfID), and the multilateral development banks, are all, to
37 different extent, supporters of the various climate risk pooling initiatives now operational in developing
38 countries.

39 As noted also in IPCC AR5, risk sharing and risk transfer strategies provide 'pre-disaster financing
40 arrangements that shift economic risk from one party to another' (IPCC 2012). Risk pooling among
41 countries and regions is relatively advantageous when compared to conventional insurance because of
42 the effective subsidizing of 'affected regions' using revenues from unaffected regions which involve
43 pooling among a large subset of countries (Lucas 2015) (*high confidence*). In general, the premiums are
44 less costly than what an individual country or entity can achieve and disbursement is rapid and there
45 are also fewer transaction costs (Lucas 2015; World Bank 2015). The World Bank argues that the
46 experience with Pacific Catastrophe Risk Insurance Pilot (PCRIP) and Africa Risk Capacity risk
47 pooling (ARC) show saving of 50% in obtaining insurance cover for pooled risk compared with
48 purchasing comparable coverage individually (Lucas 2015; World Bank 2015; ARC 2016). However,

1 it requires, as noted by UNESCAP, ‘extensive coordination across participating countries, and entities’
2 (Lucas 2015).

3 At the same time, this approach has substantial basis risk, (actual losses do not equal financial
4 compensation) (Hermann et al. 2016) (*high confidence*). With parametric insurance, pay-out are pre-
5 defined and based on risk modelling rather than on the ground damage assessment so may be less than,
6 equal to, or greater than the actual damage. It does not cover actual losses and damage and therefore,
7 may be insufficient to meet the cost of rehabilitation and reconstruction. It may also be ‘non-viable’ or
8 damaging to livelihood in the long run (UNFCCC 2008; Hellmuth et al. 2009; Hermann et al. 2016).
9 Additionally, if the required threshold is not met, there may be no pay-out, though a country may have
10 experienced substantial damages from a climatic event. (This occurred for the Solomon Islands in 2014
11 which discontinued its insurance with the Pacific Catastrophe Risk Insurance Pilot when neither its
12 Santa Cruz earthquake nor the 2014 flash floods were eligible to receive a pay-out under the terms of
13 the insurance (Lucas 2015).

14 Increasingly, climate risk insurance scheme is being blended into disaster risk management as part of a
15 comprehensive risk management approach (*high confidence*). The best-known example is the Caribbean
16 Catastrophe Risk Insurance Facility (CCRIF SPC 2018), which involves cooperation among Caribbean
17 states, Japan, Canada, UK and France and international organizations such as World Bank (UNESCAP
18 2017). But there are growing platforms of such an approach mainly under the umbrella of the G7’s
19 InsuResilience Initiative (Deutsche Klimafinanzierung 2020), including, the Pacific Catastrophe Risk
20 Assessment and Financing Initiative) for the Pacific Islands, the African Risk Capacity (ARC Agency
21 and its financial affiliate), and the African Risk Capacity Limited (ARC Ltd/ the ARC Group) (ARC
22 2016) and in the Asian region, the South East Asian Disaster Risk Insurance Facility (SEADRIF) and
23 the ASEAN Disaster Risk Financing and Insurance Program (ADRFI), (SEADRIF 2018; GIZ and
24 World Bank 2019; Martinez-diaz et al. 2019; Vyas et al. 2019; World Bank 2019a). The group of 20
25 vulnerable countries (V-20) has also developed a Sustainable Insurance Facility (SIF), billed as
26 technical assistance facility for climate-smart⁵ insurance for MSMEs in 48 developing countries as well
27 as potentially to de-risk renewable energy in these countries and regions (ACT Alliance 2020; V20
28 2020, 2021).

29 However, as noted above, climate risk pooling is not a panacea. There are very obvious and significant
30 challenges. According to (Kreft and Schäfer 2017), limitations of insurance schemes, include
31 coordination challenges, limited scope, de-stabilization due to exit of one or more members as
32 premiums risk and inadequate attention to permanent (Schaeffer et al. 2014). There are also challenges
33 with risk diversification, replication, and scalability (*high confidence*). For example, CCRIF is
34 extending both its membership and diversifying its geographic dimensions into Central America in
35 seeking to lower covariate risk (similar shocks among cohorts such as droughts or floods). Under the
36 SPC portfolio, CCRIF is able to segregate risk across the regions. Risk insurance does not obviate from
37 the need to engage in capacity building to scale-up as well as having process for addressing systemic
38 risk. Currently, risk pools have limited sectoral reach and may cover agriculture but not other important
39 sectors such as fisheries and public utilities. Only recently (July 2019) has CCRIF initiated coverage of
40 fisheries with the development of its he Caribbean Oceans and Aquaculture Sustainability Facility
41 (COAST) instrument (CCRIF SPC 2019; ACT Alliance 2020). Historically, risk pool mechanisms, like

FOOTNOTE⁵ According to the V20, ‘the term “climate-smart” captures the need for two types of climate-related insurance products for MSMEs in vulnerable economies: (1) Climate risk insurance (2) Insurance products which enable low carbon investments, and thereby contribute to increased efficiencies through cost-savings from cheaper low-carbon technologies (2021).

1 CCRIF and ARC, only cover a small subset of perils, such as tropical cyclone, earthquake and excess
2 rainfall but do not include other perils such as drought. Since 2016, ARC has increased its scope to
3 cover drought and in 2019 launched ARC Replica which not only covers drought but offers premiums
4 and coverage to NGOs and the World Food Programme through the START Network and a pastoral
5 drought product for protecting small farmers and ensuring food security. In some regions and countries,
6 there may also be limited access to reinsurance (Schaeffer et al. 2014; Lucas 2015). An important down-
7 side of climate risk pooling is that it does not cover the actual cost of damage and losses. Though on
8 the positive side, pay-out may exceed costs, but it may also be less than cost. Hence, the parametric
9 approach is not a panacea and does not preclude having recourse to conventional indemnity insurance,
10 which will cover full damage costs after a climate change event as it involves full on the ground
11 assessment of factors such as the necessity and costs of repair versus say replacement value of damaged
12 infrastructure. This may be important for governmental and publicly provided services such as schools,
13 hospitals, roads, airports, communications equipment and water supply facilities. Given the growing
14 popularity of parametric insurance and climate risk pooling, there are very ambitious attempts to
15 expand this approach on several fronts (Scherer 2017). (Schoenmaker and Zachmann 2015) have
16 proposed a global climate risk pool to help the most vulnerable countries. The pathway to this includes
17 capacity building in underdeveloped financing sectors of developing countries. They argue that as
18 climate extreme become more normalised, they will wipe out significant part of the infrastructure and
19 productive capacity of developing countries. This will have knock-on impact on fiscal capacity due to
20 lowered tax revenue and high rebuilding costs. ‘Developing countries, (Schoenmaker and Zachmann
21 2015) argue, ‘cannot insure against such event on a market basis, nor would it be sensible to divert scare
22 fiscal resources away from infrastructure investment into accumulating a financial buffer for such a
23 situation (Schoenmaker and Zachmann 2015). In that context, (Schoenmaker and Zachmann 2015) call
24 for international risk pooling as ‘the only sensible strategy’ especially if it addresses the major gaps in
25 climate risk insurance for poor and vulnerable communities by enhancing demand through ‘smart
26 support instrument’ for premium support such as full or partial premium subsidies and investment in
27 providing risk reduction (Schäfer et al. 2016; Le Quesne et al. 2017; MCII 2018; Vyas et al. 2019). This
28 it is argued may help to smoothen out the limited uptake of regional institutions such as ARC, CCRIF
29 SPC which are only in three regions of the world (with missing mechanism in South America). (Kreft
30 and Schäfer 2017). Existing regional mechanisms, while they may perform very well, only cover a
31 portion of climatic hazards and tend to have limited subscribers. For example, across the key four
32 sovereign risk pools (ARC, CRIFSPC, PCRAFI and SEADRIF), though there are 68 countries only 1/3
33 or 32% have purchased coverage in 2019 and 46% ‘did not deploy disaster risk financing instruments
34 (ACT Alliance 2020).

35 Other gaps and challenges flagged by (Kreft and Schäfer 2017) include limited coverage of the full
36 spectrum of contingency risks experienced by countries, inadequate role of risk management as a
37 standard for all regional pools, though there are some emerging best practices in terms of data provision
38 on weather-related risks, and incentivization of risk reduction (*high confidence*). Here, they recognise
39 the work of ARC’s Africa Risk Capacity for not only providing the infrastructure to trigger
40 disbursement but for also promoting national risk analysis. Another important gap in the landscape of
41 climate risk pooling is lack of attention to financial institutions’ lending portfolio that is vulnerable to
42 weather shocks. In this regard subsidies as part of innovative financing schemes facilitated by the donor
43 community can encourage the uptake of meso-level climate risk insurance solutions (Kreft and Schäfer
44 2017).

45 In the literature, there are two attempts at systematic evaluation or comprehensive assessment of
46 regional climate risk pools. A comprehensive study by (Scherer 2017) and FCDO ten-year evaluation
47 (2015-2024). Overall, none of these studies draw adverse conclusions about regional climate risk
48 pooling initiatives/mechanisms. According to Scherer ‘it appears that insurances work in principle and
49 there is certainly successes’ and ‘initial experiences demonstrate regional climate risk insurances
50 works’. The author cited the 28 pay-outs to 16 countries of 106 million USD arguing that it provides

1 cash-starved countries with much needed cash (Scherer 2017, p. 4). The FCDO study examines the
2 uptake of ARC and its impact on reducing vulnerability to disasters. It notes that there is scarce literature
3 on disaster risk insurance mechanism in terms of impacts. In its current sample of 20 countries as of
4 November 2017, 4 are projected to experience food security crisis (IPC Level 3) but are not signatories
5 to the ARC which may signal that ARC is not attractive to all food insecure countries and that there is
6 no overwhelming appetite for ARC among poorer countries. Additionally, (Panda and Surminski 2020),
7 research on the importance of indicators and frameworks for monitoring the performance and impact
8 of CDRI make no final assessment of any of the regional climate risk pool. However, they propose
9 mechanisms to improve the transparency and accountability of the system. Both (Scherer 2017), (Forest
10 2018) and (Panda and Surminski 2020), seems to indicate that ‘there is enthusiasm to support and scale
11 up regional climate risk insurance’ (Scherer 2017, p. 4) Examples of this support include, the Germany
12 Ministry for Economic Cooperation and Development (BMZ) has provided 5.9 million USD for WFP
13 to protect 1.2 million vulnerable African framers with climate risk insurance, through ARC Replica,
14 and the G7, InsuResilience Vision 2025, which has committed to ensuring 400–500 million poor
15 persons are covered against disaster shock by pre-arranged finance and insurance mechanism by 2025,
16 some of this will be through ARC (WFP 2020). Of course, this does not mean that risk pools are without
17 challenges or are not failing on specific sets of metrics. (Forest 2018) flags three failings areas: policy
18 holder and hazard coverage, the cost of premium and risk transfer parameters and the use of pay-out,
19 which in most cases are up to the government. Here, ARC is flagged among the three regional Risk
20 pools, as the only one with contingency plan requirement that can support effective use of pay-outs.
21 Other research exploring climate risk pool and its impacts, flag lack of transparency around pay-out,
22 premium or risk transfer parameters. Ultimately, climate risk pools are not full insurance; they offer
23 only limited coverage. Entities such as the UK Anti-Corruption Help desk is exploring how to mitigate
24 potential corruption with regard to climate risk insurance.

25

26 **15.6.5 Widen the focus of relevant actors: Role of communities, cities and sub-national** 27 **levels**

28 There is an urgency and demand to meet the financial needs of the climate change actions not only at
29 the national level but also at the subnational level, to achieve low-carbon and climate-resilient cities
30 and communities (Barnard 2015; Moro et al. 2018) (*high confidence*). Scaling up subnational climate
31 finance and investment is a necessary condition to achieve climate change mitigation and adaptation
32 action (Ahmad et al. 2019).

33 **The importance of exploring effective subnational climate finance.** Stronger subnational climate
34 action is indispensable to adapt cities to build more sustainable, climate-positive communities
35 (Kuramochi et al. 2020). It has transformative potential as a key enabler of inclusive urban economic
36 development through the building of resilient communities (Floater et al. 2017a; Colenbrander et al.
37 2018b; Ahmad et al. 2019) (*high confidence*). Yet the significant potential of subnational climate
38 finance mechanisms remains unfulfilled. Policy frameworks, governance, and choices at higher levels
39 underpin subnational climate investments (Colenbrander et al. 2018b; Hadfield and Cook 2019). To
40 scale climate investment, a systematical understanding of the preconditions to mobilizing high-potential
41 financing instruments at the national and subnational levels is necessary.

42 **Subnational climate finance needs and flows.** Subnational climate finance covers financing
43 mechanisms reaching or utilizing subnational actors to develop climate positive investment in urban
44 areas. The fragility of interconnected national and subnational finances affects subnational finance
45 flows, including the impact of the social-economic crisis (Canuto and Liu 2010; Ahrend et al. 2013).
46 The effect of deficit in investment for global infrastructure towards the growing subnational-level debt
47 also creates pressure on subnational finances and constrains future access to financing (Smoke 2019)
48 (*high confidence*).

1 The International Finance Corporation estimates a cumulative climate investment opportunity of 29.4
2 trillion USD across six urban sectors (waste, renewable energy, public transportation, water, electric
3 vehicles, and green buildings) in emerging market cities, cities in the developing country with more
4 than 500,000 population, to 2030 (IFC 2018). However, State of Cities Climate Finance report estimated
5 that an average of USD 384 billion was invested in urban climate finance annually in 2017-2018
6 (Negreiros et al. 2021). The Institute for Environment and Development estimates that out of the 17.4
7 billion USD total investments in climate finance, less than 10% (1.5 billion USD) was approved for
8 locally-focused climate change projects between 2003 and 2016 (Soanes et al. 2017).

9 **Subnational climate public and private finance.** Urban climate finance and investment are prominent
10 among the subnational climate finance landscape (CCFLA 2015; Buchner et al. 2019). Finance
11 mechanisms that can support climate investment for the urban sector include public-private partnerships
12 (PPPs); international finance; national investment vehicles; pricing, regulation, standards; land value
13 capture; debt finance; and fiscal decentralization (Granoff et al. 2016; Floater et al. 2017b; Gorelick
14 2018; White and Wahba 2019). Among these mechanisms, PPPs, debt finance, and land value capture
15 have the potentials to mobilise private finance (Ahmad et al. 2019). Better standardization in processes
16 is needed, including those bearing on contracts and regulatory arrangement, to reflect local specificities
17 (Bayliss and Van Waeyenberge 2018) [Reference to Public private mobilization Section in 15.6.1.1].

18 PPPs are particularly important in cities with mature financial systems as the effectiveness of PPPs
19 depends on appropriate investment architecture at scale and government capacity (*high confidence*).
20 Such cities can enable its infrastructure such as renewable energy production and distribution, water
21 networks, and building developments to generate consumer revenue streams that incentivise private
22 investors to purchase equity as a long-term investment (Floater et al. 2017b).

23 National-level investment vehicles can provide leadership for subnational climate financing and crowd
24 in private finance by providing early-stage market support to technologies or evidence related to asset
25 performance and costs-benefits (*high confidence*). The use of carbon pricing is increasing at the
26 subnational level along with regulation and standards on negative externalities, such as pollution, to
27 steer investment towards climate financing (World BankGroup 2019).

28 Debt financing via subnational bonds and borrowing, including municipal bonds, is another potential
29 tool for raising upfront capital, especially for rich cities (*high confidence*). The share of sub-national,
30 sub-sovereign, and sovereign bonds could grow over time, given efforts to expand the creditworthiness
31 and ensure a sufficient supply of own-source revenue to reduce the default risk. As of now, subnational
32 and sub-sovereign bonds are constrained by public finance limits and the fiscal capacities of
33 governments. However, while green bonds have potential for growth at the subnational level and may
34 result in a lower cost of capital in some cases, the market faces challenges related to scaling up and has
35 been associated with limited measurable environmental impact to date (see Section 15.6.8 Innovative
36 Financial Products for further discussion). Further, bonds with lower credit ratings drive higher issuance
37 costs for climate risk cities, e.g., costs related to disclosure and reporting (Painter 2020).

38 **Key challenges of subnational climate finance.** Across all types of cities, five key challenges constrain
39 the flow of subnational climate finance (*high confidence*): (i) difficulties in mobilizing and scaling-up
40 private financing (Granoff et al. 2016); (ii) deficient existing architecture in providing investment on
41 the scale and with the characteristics needed (Anguelovski and Carmin 2011; Brugmann 2012); (iii)
42 political-economic uncertainties, primarily related to innovation and lock-in barriers that increase
43 investment risks (Unruh 2002; Cook and Chu 2018; White and Wahba 2019)); (iv) the deficit in
44 investment for global infrastructure affects the growing subnational-level debt (Canuto and Liu 2010)
45 and; (v) insufficient positive value capture (Foxon et al. 2015).

46 **Different finance challenges between rich and poor cities.** Access to capital markets has been one of
47 major sources for subnational financing is generally limited to rich cities, and much of this occurs

1 through loans (*high confidence*). Different challenges accessing capital markets associated with wealthy
2 and poorer cities are compounded into three main issues: (i) scarcity and access of financial resources
3 (Bahl and Linn 2014; Colenbrander et al. 2018b; Cook and Chu 2018; Gorelick 2018), (ii) the level of
4 implication from the existing distributional uncertainties to the current financing of infrastructural
5 decarbonization across carbon markets (Silver 2015), and (iii) the policy and jurisdictional ambiguity
6 in urban public finance institutions (Padigala and Kraleti 2014; Cook and Chu 2018). In poorer cities,
7 these differing features continue to be inhibited by contextual characteristics of subnational finance,
8 including gaps in domestic and foreign capital (Meltzer 2016), the mismatch between investment needs
9 and available finance (Gorelick 2018), weak financial autonomy, insufficient financial maturity,
10 investment-grade credit ratings in local debt markets (Bahl and Linn 2014), scarce diversified funding
11 sources and stakeholders (Gorelick 2018; Zhan et al. 2018; Zhan and de Jong 2018) and weak enabling
12 environments (Granoff et al. 2016).

13 The depth and character of the local capital market also affect cities differently in generating bonds
14 (*high confidence*). Challenges facing cities in developing countries include insufficient appropriate
15 institutional arrangements, the issues of minimum size, and high transaction costs associated with green
16 bonds (Banga 2019). Green projects and project pipelines are generally smaller in scale feasible for a
17 bond market transaction (Saha and D’Almeida 2017; DFID 2020). De-risking in the different phases of
18 long-term project financing can be promoted to improve appetite of capital market [Reference to
19 development of local capital markets Section in 15.6.7].

20 **Climate investment and finance for communities.** There is insufficient evidence that which financing
21 schemes contribute to climate change mitigation and adaptations at community level (*high confidence*).
22 There is growing interest in the linkages between microfinance and adaptation on the agriculture sector
23 (Agrawala and Carraro 2010; Fenton et al. 2015; Chirambo 2016; CIF 2018; Dowla 2018), the finance
24 for community-based adaptation actions (Fenton et al. 2014; Sharma et al. 2014), and the relations
25 between remittances and adaptation (Le De et al. 2013). However, there is less discussion on community
26 finance aside from the benefits of community finance and village funds in contributing to close
27 investment gaps and community-based mitigation in the renewable energy and forest sectors (Ebers
28 Broughel and Hampl 2018; Bauwens 2019; Watts et al. 2019) The full potential and barriers of the
29 community finance model are still unknown and research needs to expand understanding of favourable
30 policy environments for community finance (Bauwens 2019; Watts et al. 2019).

31 **Implications for the transformation pathway.**

32 Cities often have capacity constraints on planning and preparing capital investment plans. An integrated
33 urban capital investment planning is an option to develop cross-sectoral solutions that reduce
34 investment needs, boost coordination capacity, and increase climate-smart impacts (Negreiros et al.
35 2021) (*high confidence*). In countries with weak and poorly functioning intergovernmental systems,
36 alliances and networks may influence their organizational ability to translate adaptive capacity for
37 transformation into actions (Leck and Roberts 2015; Colenbrander et al. 2018a). Deepening
38 understanding of country-specific enabling environment for mobilizing urban climate finance among
39 and within cities and communities, design of policy, institutional practices and intergovernmental
40 systems are needed to reduce negative implications of transformation (Steele et al. 2015).

41 **15.6.6 Innovative financial products**

42 Innovative financial products with increased transparency on climate risk have attracted investor
43 demand, and can facilitate investor identification of low carbon investments (*high confidence*).
44 Innovative products may not necessarily increase financial flows for climate solutions in the near term,
45 however they can help build capacity on climate risk and opportunities within institutions and
46 companies to pave the way for increased flows over time.

1 **Investor demand is driving developments in innovative financial products** (*high confidence*). Since
2 AR5, innovative financial products such as sustainability and green labelled financial products have
3 proliferated (see financial stock estimates in Section 0). These financial products are not necessarily
4 ‘new’ in terms of financial design but are packaged or labelled in an innovative way to attract
5 responsible and impact-oriented institutional investors.

6 The growth and diversity of the green bond market illustrates how innovative financial products can
7 attract both public and private investors (*high confidence*). Demand for green financial products initially
8 stemmed from public sector pension funds. Pension funds and insurance companies in OECD countries
9 have traditionally favoured bonds as an asset class with lower risk (OECD and Bloomberg 2015).

10 Since AR5, labelled green bonds have grown significantly, exceeding 290 billion USD issued in 2020
11 with a total of 1.1 trillion USD in outstanding bonds (CBI 2021a) (see also local capital markets Section
12 15.6.7). Corporates, financial institutions and government-backed entities (e.g. in real estate, retail,
13 manufacturing, energy utilities) issued the largest volumes, with use of proceeds focused primarily on
14 GHG mitigation in energy, buildings and transport projects (CBI 2021a). Given their focus on GHG
15 mitigation, green bonds are also sometimes referred to as climate bonds, but the common market
16 terminology is ‘green’. Municipal green bond issuance has also been growing (see further discussion
17 on municipal green bonds in Section 15.6.7 on local actors). Beyond green bonds, additional products
18 such as green loans, green commercial paper, green initial public offerings (IPOs), green commodities,
19 and sustainability-linked bonds and loans have also been introduced in the market (CBI 2019a) (see
20 discussion on building yield curves in local capital markets Section 15.6.7).

21 Investor demand for green bonds is evidenced by over-subscription of deals. Recent studies indicate an
22 over-subscription for green labelled bonds by an average of between three and five times, as compared
23 to non-labelled bonds (Gore and Berrospi 2019; Nauman 2020). Results of a survey of global treasurers
24 showed a higher demand for green bonds than non-labelled bonds for 70% of the respondents (CBI
25 2020a).

26 The financial crisis associated with COVID-19 has put increased pressure on debt issuers, and the extent
27 to which the increase in indebtedness for sovereigns and corporates has been financed via climate-
28 related labelled debt products is not known. Further, at this time there is no identified literature assessing
29 the degree to which international versus domestic investors are financing sovereign green debt in
30 developing countries (for further discussion on attracting different types of investors through the
31 development of local capital markets Section 15.6.7) However, since the onset of the COVID-19 crisis,
32 continued steady growth in issuance has been observed broadly across sustainable bonds (including
33 green, social and sustainability bonds), with more significant growth in social bonds to support the
34 COVID-19 recovery (Maltais and Nykvist 2020; CBI 2021a).

35 Index providers and exchanges can also play a supporting role in transparency for identification of
36 benchmarks and innovative financial products for climate action. Low-carbon indices have proliferated
37 in recent years, with varying approaches including reduced exposure to fossil, best-in-class performers
38 within a sector, and fossil-free (UN PRI 2018) (see discussion on ESG index performance that follows
39 in this section). Indices can provide transparency on low-carbon opportunities making it simpler for
40 funds and investors to identify green investment options. Exchanges can also play a supporting role to
41 the uptake of green financial products through transparent listings and requirements to improve
42 credibility of green labelling. The number of green or sustainability bond listing segments tripled from
43 five in 2016 to 15 in 2018 (SSE 2018). Green security listings can also be used to enhance local capital
44 markets (see Section 15.6.7 for further discussion).

45 **Significant potential exists for continued growth in innovative financial products, though some**
46 **challenges remain** (*high confidence*). Despite recent growth and diversification, green bonds face
47 several challenges in scaling up. Issuance of green-labelled bonds constitutes approximately 1% of the

1 global bond market issuance (ICMA 2020b; CBI 2021a) Potential exists to increase issuance amongst
2 corporates, for instance, and across a broader regional scope (although subject to limitations of local
3 capital markets). Yet there remain several challenges to growing the green bond market, including *inter*
4 *alia* concerns about greenwashing and limitations in application to developing countries (Shishlov et
5 al. 2018; Banga 2019).

6 There is no globally accepted definition of green bonds, and varied definitions of eligible green
7 activities are evolving across regional bond markets. Beyond the most commonly used green label,
8 other related labels such as blue, sustainable, transition, sustainable development goal (SDG), social
9 and environmental, social and governance (ESG) have some overlapping applications (Schumacher
10 2020). The degree to which these labels represent climate relevant investments depend on underlying
11 criteria and how they are applied (see also discussion in local capital markets Section 15.6.4).

12 There are several initiatives aimed at protecting the integrity of the green label. Guidance on use and
13 management of proceeds established by the International Capital Markets Association's Green Bond
14 Principles (GBP) is followed on a voluntary basis, which notes eligible use of proceeds as primarily
15 climate mitigation and adaptation projects. The GBP also recommend independent external reviews at
16 the time of issuance, with 89% of green bond issuers in 2020 with external reviews at the time of
17 issuance (CBI 2021a). In addition to best practice based on voluntary principles, a further check on
18 greenwashing, although insufficient on its own, is the fear of reputation risk on behalf of investors,
19 issuers and intermediaries in the age of social media (Hoepner et al. 2017; Deschryver and de Mariz
20 2020). A report on post-issuance green bond impact reporting notes that despite concerns (Shishlov et
21 al. 2018), greenwashing incidence is rare, with 77% of green bond issuers reporting on allocation and
22 59% reporting on impact, but with significant variance in quality and consistency of impact reporting
23 (CBI 2021b).

24 Financial disclosure regulatory developments can help further align and specify definitions of green in
25 the financial sector but are not a substitute for climate policy (*high confidence*). Developing a common
26 basis for understanding a green label could further reduce uncertainty or concerns of greenwashing.
27 Regulatory developments in some regions seek to further guard against greenwashing with more
28 specific definitions. The EU sustainable finance package, including the EU Taxonomy and EU Green
29 Bond Standard draft regulations, is the broadest reaching, but not the only, regional initiative focused
30 on disclosure of climate risk (see also Section 15.6.3). Taxonomies across regions are not always
31 aligned on what can constitute a green project, for example with respect to transition activities
32 (International Capital Market Association 2021) (see also discussion on local capital markets in Section
33 15.6.7). While standardisation can help reduce uncertainty in markets with imperfect knowledge, the
34 green bond market is currently developing and is expected to continue to reflect regional differences in
35 economic governance approaches (Nedopil et al. 2021). Regulations may also have trade-offs in terms
36 of transaction costs for green financial product issuers. Classification approaches can also face
37 challenges, depending on how they are designed, in their ability to capture new technologies and social
38 impacts (see Section 15.4).

39 Green bonds have been primarily targeting climate mitigation projects, with far fewer projects identified
40 as adaptation. Green bonds mainly finance projects in the energy, buildings and transportation sectors,
41 which constituted 85% of the use of proceeds of green bonds in 2020 (CBI 2020b, 2021a). Agriculture
42 and forestry projects, including adaptation projects, have been less suited to be financed in a bond
43 structure, which could be in part due to the more dispersed and smaller nature of the projects and in part
44 due to project 'bankability' or ability to contribute steady streams of financing to pay back the terms of
45 a bond. However, adaptation projects may not be identified as such as resiliency becomes more
46 mainstreamed into infrastructure planning (see Section 15.3.2)

47 While green bonds have the potential to further support financial flows to developing countries, local
48 capital markets can be at varying stages of development (see discussion in Section 15.6.2 on enabling

1 environments and in Section 15.6.7 on local capital markets for peer-learning examples and de-risking
2 opportunities) (Banga 2019). While multilateral and bilateral development finance institutions have
3 been active in the green bond market, global issuance in 2020 in the top 10 countries included only one
4 developing country (CBI 2021a). Targeting international investors can be enhanced via de-risking
5 activities (see further discussion in section 15.6.4).

6 **Identifying green financial products can increase uptake and may result in a lower cost of capital**
7 **in certain parts of the market** (*high confidence*). Investors face a systematic under-pricing of climate
8 risk in financial markets (Krogstrup and Oman 2019; Kumar et al. 2019). Transparent identification of
9 financial products can make it easier for investors to include low carbon products in their portfolios.
10 Investors with mandates that include or are focused on climate change are showing an interest in green-
11 labelled financial products. Investors that identify themselves as green constitute approximately 53%
12 of the investor base for green bonds in the first half of 2019 (CBI 2019b).

13 There is some evidence of a premium, or an acceptance of lower yields by the investor, for green bonds
14 (*medium confidence*). A survey of recent literature finds some consensus of the existence of a green
15 premium in 56% of the studies on the primary markets (with a wide variance of premium amount), and
16 70% of the studies on the secondary market (with an average premium of -1 to -9 basis points),
17 particularly for government issued, investment grade and green bonds that follow defined governance
18 and reporting practices (MacAskill et al. 2021). In the US municipal bond market, as credit quality for
19 green labelled bonds has increased in the past few years, some studies show a positive premium for
20 green bonds is arising (Baker et al. 2018; Karpf and Mandel 2018), or appearing only in the secondary
21 market (Partridge and Medda 2020), while others find no evidence of a premium (Hyun et al. 2019;
22 Larcker and Watts 2020). Several studies also show a recent emergence of a premium and
23 oversubscription for some green labelled bonds denominated in EUR (CBI 2019b), in some cases for
24 both USD or EUR (Ehlers and Packer 2017) green bonds, with a wide variation in the range of the
25 observed difference in basis points focusing on the secondary market (Gianfrate and Peri 2019;
26 Nanayakkara and Colombage 2019; Zerbib 2019), with financial institution and corporate green bonds
27 exhibiting a marginal premium compared with their non-green comparisons (Hachenberg and Schiereck
28 2018; Kempa et al. 2021).

29 Spill over effects of green bonds may also impact equity markets and other financing conditions. Stock
30 prices have been shown to positively respond to green bond issuance (Tang and Zhang 2020). One study
31 linked enhanced credit quality induced by issuing green labelled bonds to a lower cost of capital for
32 corporate issuers (Agliardi and Agliardi 2019). Issuers' reputation and use of third-party verification
33 can also improve financing conditions for green bonds (Bachelet et al. 2019). Green bonds are strongly
34 dependent on fixed income market movements and are impacted by significant price spill over from the
35 corporate and treasury bond markets (Reboredo 2018). A simulation of future green sovereign bond
36 issuances shows that this can promote green finance via firm's expectations and the credit market
37 (Monasterolo and Raberto 2018).

38 **Financial flows via these instruments have limited measurable environmental impact to date,**
39 **however they can support capacity building on climate risk and opportunities within institutions**
40 **to realise future impacts** (*high confidence*). There is a lack of evidence to date that green and
41 sustainable financial products have significant impacts in terms of climate change mitigation and
42 adaptation (see also Box 15.7). Further, new products must be coupled with tightened climate policy
43 and a reduction in investments associated with GHG-emitting activities to make a difference on the
44 climate (see section 15.3.3.2 for further discussion on reduction of financial flows to emitting activities).
45

46 It is challenging to link specific emission reductions with specific instruments that mainly target climate
47 activities such as green bonds. Data challenges point to an inability to link emission reductions,
48 including Scope 3 GHG emissions, at the organization or firm level with green bond use-of-proceeds

1 issuance (Ehlers et al. 2020; Tuhkanen and Vulturius 2020). However one study found evidence of a
2 signalling effect of issuing green bonds resulting in emission reductions at the corporate level following
3 issuance (Flammer 2020), and another study characterised the lifecycle emissions of renewable energy
4 financed by green bonds, indicating potentially substantive avoided emissions but with variance up to
5 a factor of 12 across bonds depending on underlying assumptions (Gibon et al. 2020). There is also a
6 lack of impact reporting requirements and consistency in the green bond market. Impact reporting is
7 not typically required for green bond listings on specific exchanges, nor are there any requirements for
8 independent reviews of impact reporting, however this could change in future if investors apply
9 pressure.

10 Green-labelled products may not necessarily result in increased financial flows to climate projects,
11 although there can be benefits from capacity building with issuing institutions. Green bonds can be used
12 to finance new climate projects or refinance existing climate projects, and thus do not necessarily result
13 in finance for new climate projects constituting additional GHG reductions (a framing used in the Clean
14 Development Mechanism). The labelling process itself may not necessarily lead to additional financing
15 (Dupre et al. 2018; Nicol et al. 2018b). However, the labelling process has merit in contributing to
16 building capacity within issuing institutions on climate change (Schneeweiss 2019), which could
17 support identification of new green projects in the pipeline.

18 Climate risk disclosure initiatives, some of which are voluntary in nature, may have a limited direct
19 climate impact. Transparency on climate risk may not change investor decisions nor result in
20 divestment, especially in the emerging economies, as support and clear direction from regulatory and
21 policy mechanisms are required to drive institutional investors at large (Ameli et al. 2021c). On the
22 other hand, there is evidence of reduced fossil fuel investments following mandatory climate risk
23 disclosure requirements, indicating a broader signalling effect of transparency (Mésonnier and Nguyen
24 2021).

25 *** START BOX 15.7. HERE ***

26 **Box 15.7 Impact of ESG and sustainable finance products and strategies**

27 While scaling up climate finance remains a challenge (see Section 15.3.2), there is consensus that
28 investments that are managed taking into account broader sustainability criteria have increased
29 consistently and ESG integration into sustainable investment is increasingly being mainstreamed by the
30 financial sector over the last years (Maiti 2021). The United Nations Principles for Responsible
31 Investment (PRI) grew to over 3000 signatories in 2020, representing over USD 100 trillion in assets
32 under management (UN PRI 2020). And according to the 2018 biennial assessment by Global
33 Sustainable Investment Alliance⁶, sustainable investments in five major developed economies grew by
34 34% in the two year period following the 2016 assessment. The primary ESG approaches leveraged
35 were exclusion criteria and ESG integration, which together amounted to over USD 37 trillion,
36 accounting for two-thirds of the assessed sustainable investments, with novel strategies such as best-in
37 class screening and sustainability themed investing showing significant growth, although together they
38 accounted for around 6 percent of these investments (GSIA 2019). Shareholder activism or corporate
39 engagement is the other key approach, which has been well established and continued to grow to nearly
40 USD 10 trillion (GSIA 2019).

41 However, research indicates that ESG strategies by themselves, do not yield meaningful social or
42 environmental outcomes (Kölbel et al. 2020). When it comes to the tangible impact of the financial
43 sector on addressing climate change and sustainable development, there remains ambiguity. There is a
44 growing need for more robust assessment of ESG scores, including establishing higher standardization

FOOTNOTE⁶ GSIA is an international collaboration of membership-based sustainable investment organizations.

1 of scoring processes and a common understanding of the different ESG criteria and their tangible impact
2 on addressing climate change. The issue was highlighted in an assessment of six of the leading ESG
3 rating agencies' company ratings under the MIT Aggregate Confusion Project, which found the
4 correlation among them to be 0.61, leading them to conclude that available ESG data was "noisy and
5 unreliable" (Berg et al. 2020). This need is reaffirmed by (Drempetic et al. 2020), who claim that a
6 thorough investigation of ESG scores remains a relatively neglected topic, with extraneous factors, such
7 as firm size, influencing the score (Drempetic et al. 2020).

8 There continues to be a research gap in assessing the direct impact of ESG and sustainable investments
9 on climate change indicators, with most existing studies assessing the co-relation between either the
10 factors driving the sustainable finance trends and the impact on sustainable investments, or sustainable
11 investments and the impact on corporate financial performance. Nevertheless, since the post SDG
12 adoption period, there has been a notable uptake on research linking sustainable business practices and
13 financial performance (Muhmad and Muhamad 2020a). This research shows that there is a growing
14 business case for ESG investing, with evidence increasingly indicating a non-negative co-relation
15 between ESG, SDG adoption and corporate financial performance (Friede et al. 2015; Muhmad and
16 Muhamad 2020b), and ESG performance having a positive relation with stock returns (Consolandi et
17 al. 2020). Research, focused on developed economies, also indicates towards a positive relation between
18 ESG criteria and disclosure, and economic sustainability of a firm (Giese et al. 2019; Alsayegh et al.
19 2020) and allays investor fears by showing that sustainable finance initiatives, such as divestment,
20 doesn't adversely impact investment portfolio performance (Henriques and Sadorsky 2018; Trinks et
21 al. 2018). It should be reiterated, that this research assesses the co-relation between ESG criteria and
22 corporate financial performance, with the researchers in some cases, such as (Friede et al. 2015),
23 including disclaimers of the results being inconclusive and highlighting the need for a deeper
24 assessment for linking ESG criteria with impact on financial performance.

25 On the other hand, there is growing evidence for a sustainable investment lens having a broader positive
26 impact on creating an enabling environment and strengthening the case for such investments. For
27 instance, CSR activities and investments on the environment dimension, specifically in the areas of
28 emission and resource reduction, were found to be profitable and a predictor of future abnormal returns
29 in the longer term, from additional cash flow and additional demand (Dorfleitner et al. 2018). These
30 factors could be contributing to the increasing trend of sustainable and green investments, and can said
31 to be further reiterated by the spate of investor led collaborative initiatives and recent announcements
32 by leading finance institutes in the developed economies, which is well recorded in a range of recent
33 grey literature, including new climate-aligned investment strategies and ambition towards net zero
34 targets.

35 Yet there is also a risk of companies announcing projected sustainability or net zero targets and claiming
36 the associated positive reputational impact, while having no clear action plan in place to achieve these.
37 The lack of mandatory reporting frameworks, which results in an over-reliance on self-reported carbon
38 data by companies for ESG assessments, can be a primary contributor (In and Schumacher 2021).

39 While there is a lack of research on the impact of sustainable finance products, divestment impact has
40 been assessed in more detail. Although the research here also points towards the ambiguous direct
41 impact of divestment on reducing GHG emissions or on the financial performance of fossil fuel
42 companies, its indirect impact on framing the narrative around sustainable finance decisions (Bergman
43 2018), and the inherent potential of the divestment movement for building awareness and mobilizing
44 broader public support for effective climate policies, have been better researched and could be
45 considered to be the more relevant outcomes (Braungardt et al. 2019). Arguments against divestment
46 point to its largely symbolic nature, but (Braungardt et al. 2019) elaborate on the broader positive
47 impacts of divestment, which includes its ability to spur climate action as a moral imperative and
48 stigmatise and reduce the power of the fossil fuel lobby, and the potential of the approach to mitigate

1 systemic financial risks arising due to climate change and address the legal responsibilities of investors
2 merging in this regard.

3 Challenges remain with regards to overlapping definitions of sustainable and ESG investment
4 opportunities, which also vary depending on social norms and pathways. There is also a general need
5 for more extensive ESG disclosure on a corporate level, against the background of emerging mandatory
6 impact reporting for asset managers in some regions. A movement is building towards sustainable
7 investment strategies and increased sustainable development awareness in the financial sector (Maiti
8 2021; Muhmad and Muhamad 2020b), which points to the ability of civil society movements, such as
9 divestment campaigns, to have some influence on investor behaviour, although there are other
10 influences such as climate risk disclosure initiatives and regulations.

11 *** END BOX 15.7. HERE ***

12

13 15.6.7 Development of local capital markets

14 **International Situational Context.** Developing countries make up two thirds of the world population,
15 carry carbon intensive economies where 70% of investments need to be conducted to limit warming to
16 2°C. The focus for climate investments has been on China, USA, Europe, India and the G-20 (UNEP
17 2019) but studies highlight Paris and SDG attention should be devoted to Africa, LDCs and SIDS
18 (Africa Union Commission 2015; GCA-AAI 2020; Feindouno et al. 2020; Warner 2020; AOSIS 2021).
19 The “special needs, circumstances and vulnerability” of Africa, LDC and SIDS nations are recognised
20 under UNFCCC and UN agreements (UN 2009, 2015a,b,c; UNFCCC 2010, 2015; Pauw et al. 2019).
21 These nations currently contribute very little to global emissions. Developing countries with their
22 growing economies, including the vast Africa continent roughly the size of China, Europe, USA, India
23 combined (IEA 2014b, p. 20) with a 1 billion population expected to double by 2050, growing reliance
24 on fossil fuels and ‘cheap’ biomass (charcoal use and deforestation) amid rising urbanization and
25 industrialisation ambitions – collectively these nations hold large leap-frog potential for the energy
26 transition as well as risks of infrastructure lock-in. Accelerated international cooperation is a critical
27 enabler (IPCC 2018) in recognising this potential. This could mobilise global savings, scale up
28 development of local capital markets for accelerated low carbon investment and adaptation in low and
29 lower middle income countries as well as tackle illicit finance including tax avoidance leakages that
30 deprive developing countries of valuable resources (US DoJ 2009; Hearson 2014; Hanlon 2017a; US
31 DoJ 2019; UN IATFD 2021). Diversifying funding sources is important at a time hard-currency
32 Eurobond issuances reach records (Panizza and Taddei 2020; Moody’s Investors Service 2021).
33 Otherwise, the structure of voluntary, nationally oriented, and financially fragmented arrangements
34 under the Paris Agreement (see Chapter 17) could lead to ‘regional rivalry’ (SSP 3) pathways (IPCC
35 2018; Gazzotti et al. 2021). The benefits are many times greater than apparent costs in terms of expected
36 decline in global GHG emissions and attaining SDGs. These could even generate large ‘win-win’
37 opportunities back in capital source countries which will benefit from a flow back in import demand
38 (Hourcade et al. 2021a).

39 **Lessons from literature on policy options in mobilising capital for Paris and SDGs in developing**
40 **countries can be summarised as: a) development of national just transition strategies i) meet the**
41 **100 billion USD commitment on a grant-equivalent basis to support NDCs that integrate policies on**
42 **COVID-19 recovery, climate action, sustainable development and equity b) increase the leverage of**
43 **public funds on diverse sources of private capital through de-risking investments and public private**
44 **partnerships involving location-based entities with AAA rated players and institutional investors c) co-**
45 **ordination of project preparation and development of project pipelines by infrastructure co-ordinator**
46 **agencies, one-stop structuring and financing shops, project risk facilities provided by cities development**
47 **banks, green banks, world climate bank, global guarantee mechanism, and global infrastructure**

1 investment platform d) development of local currency bond markets backed-by cross-border guarantees,
2 technical assistance, remediation assets especially by regional and national players whose mandates
3 include nurturing local capital markets to support bond yield curve development and exchange listing
4 options e) adopting advances in science-based assessment methods to foster accountability i) for project
5 assessment, MRV and certification ii) for disclosures in climate, fossil fuels, SDG, debt transparency
6 and debt sustainability iii) for progress on UN systems of national accounts particularly for public sector
7 finance statistics.

8 **Whole of society approach to mobilising diverse capital.** There's no shortage of money globally: it
9 is simply that it has yet to travel to where it's most needed. One challenge is unlocking unencumbered
10 endowments to contribute to Paris and SDGs. (*high confidence*). The aggregate global wealth figures
11 exceed 200 trillion USD (Davies et al. 2016; UBS 2017; Credit Suisse 2020; Heredia et al. 2020). Some
12 developing countries have run pilots for investing in government bonds capitalising on fintech growth
13 discussed in section 15.6.6 (The Economist 2017; Akwagyiram and Ohuocha 2021). Others are
14 developing green products to encourage uptake by middle class retail investors (Eurosif 2018; HM
15 Treasury and UK DMO 2021). Millennial-aged inheritors expected to receive intergenerational
16 transfers mobilized by global citizen activism (see Chapter 2) invest in green retail and tech products
17 (UBS 2017; Capgemini 2021; Morgan Stanley 2017). Historic inequity and diaspora-related private and
18 public resources pledged and debated during the COVID-19 pandemic might have potential to
19 contribute towards Paris and SDGs (Olusoga 2015; Glueck and Friedman 2020; Hall 2020; Piketty
20 2020; Timsit 2020; Goldman Sachs 2021; Guthrie 2021; Mieu 2021; Wagner 2021). Philanthropic
21 institutions use grants, debt, equity, guarantees and issue investment grade bonds in using
22 unencumbered endowments (Manilla 2018; Covington 2020; Moody's 2020) but only about 2% of their
23 resources are dedicated to climate action (Williams 2015b; Kramer 2017; Morena 2018; Delanoë et al.
24 2021). The pandemic exemplified the unprecedented collaboration and mobilisation of multilateral and
25 scientific communities supported by the COVAX risk sharing mechanism for COVID-19 vaccines with
26 pooling of financial and scientific resources (OECD 2021d). This momentum in international
27 cooperation can be harnessed to galvanise resources including for teaching of sciences in developing
28 countries important in tackling society challenges, alleviating poverty (TWAS 2021) and inequity
29 legacies compounded by climate impacts debated by many (Henochsberg 2016; Obregon 2018; The
30 Economist 2021; Fernandez et al. 2021). Suggestions towards equitable models include "global
31 adaptation funding approaches" (Chancel and Piketty 2015), a "world climate bank" to finance climate
32 investments through long term bonds (Foley 2009; Broome 2012; Broome and Foley 2016), "cities
33 development bank" (Alexander et al. 2019) , "public debt financing models" (Rendall 2021) to share
34 the burden between generations which has precedence in history (Draper 2007; Fowler 2015).

35 **Local financial institutions with local markets knowledge could benefit from technical assistance**
36 **and partnership to scale up their potential. Institutional investors could be better mobilised** (*high*
37 *confidence*). The Global South has some 260 public development banks/PDBs representing 5 trillion
38 USD in assets with a worldwide PDB capacity to provide more than 400 billion USD yr⁻¹ of climate
39 finance (IDFC and GCF 2020). Case studies discuss the potential for diaspora bond issuance being
40 deployed for climate investments including securitisation of remittances as collateral for infrastructure
41 bonds (Ketkar and Ratha 2010; Akkoyunlu and Stern 2012; Gelb et al. 2021). Such instruments could
42 help harness diaspora remittances whose flows rose from under 100 to 530 billion USD during 1990-
43 2018 (World Bank 2019b). PDBs could benefit from technical partnership with multilaterals and other
44 local banks (Torres and Zeidan 2016). Their knowledge of local markets, can help build project
45 pipelines (see Figure 15.7) to channel local, domestic and international capital (Griffith-Jones et al.
46 2020). Institutional domestic and international investors have growing assets estimated to exceed 100
47 trillion USD (*high confidence*) (Think Ahead Institute 2020; UN PRI 2020; Halland et al. 2021; Heredia
48 et al. 2021; Inderst 2021) and could be better mobilized. Some 36 percent of total assets under
49 management (AUM) by the 100 largest asset owners come from pensions and SWFs in the Asia Pacific
50 region with the remainder split almost evenly across Europe, the Middle East, Africa and North

1 America. The largest pension fund in South Africa held about 130 billion USD AUM in 2019 and Africa
2 institutional investors held USD 1.8 trillion in 2020 (GEPF 2019; PWC 2015; Bagus et al. 2020; Irving
3 2020). UK NGO (War on Want 2016) analysis of 101 fossil fuel and mineral resources companies listed
4 on the London Stock Exchange (LSE) estimates these as holding a trillion USD assets inside Africa.
5 The LAC region, holds just about USD 1 trillion AUM (Serebrisky et al. 2015; Cavallo and Powell
6 2019).

7 **Investors with accumulated private capital are reported as looking for climate investments to**
8 **ensure Just Transition, alignment with Paris and SDGs. However, progress remains pilot, slow**
9 **and piecemeal** (*high confidence*). Global investors have published statements on their possible
10 contribution with recommendations to governments on de-risking to accelerate private sector
11 investment to support Paris aligned NDCs in developing countries (IIGCC 2015, 2017, 2018, 2020;
12 Global Investor Statement 2018; 2019). In March 2020, the UN Principles for Responsible Investment
13 (PRI), had 3,038 members representing 103 trillion USD (UN PRI 2020); another coalition of investors
14 published COVID-19 recovery plans (Investor Agenda 2020) and the Net Zero Asset Managers
15 initiative was launched in December 2020 (NZAM 2020). However, it is still unclear how these
16 pronouncements will be transformed to adequate financial flows and volumes of investment pipelines
17 ((IEA 2021e), Chapter 3). (Rempel and Gupta 2020) posit that a proportion of institutional holding is
18 in fossil fuels. Clean energy transition minerals raise ESG questions around inclusive development for
19 indigenous populations and requires changes to supply chains exploiting child labour (Herrington 2021;
20 IEA 2021a,f).

21 Options to mobilise institutional investors currently remain small pilots, relative to Paris and SDG
22 ambitions (*high confidence*). In terms of sample examples: in the *women of colour-led arena*, a Chicago
23 pension fund invested in a developing country using a *private equity fund*; (Langhorne 2021).
24 Institutional Blackrock's blended finance vehicle with OECD MDB partners focuses on developing
25 countries (Blackrock 2021). In regional AAA MDB partnerships, AfDB collaborates with Africa
26 nations through a *regional infrastructure fund* (Africa50 2020); ADB collaborates with a Philippines
27 state-owned pension fund and Dutch pension fund in using a *private equity fund* to catalyse private
28 sector (ADB 2012). A UN entity with several pooled public-private investment platforms include a
29 SDG blended finance vehicle (UN CDF 2020a,b, 2021a). Multilateral IFC blended finance fund,
30 supported by a sovereign guarantee from Sweden's SIDA and separately a 1 billion USD green bond
31 fund by IFC and Europe's Amundi asset manager buys green securities issued by developing country
32 banks financing local currency climate investments (IFC 2018; IFC 2021 2021; Amundi and IFC 2019).
33 The key parameter is the *investment multiplier*, the *ratio of private investment mobilised by a given*
34 *amount of public funds* which varies by product type. IFC's portfolio of blended finance investments
35 point to a self-reported range of 3 to 15 times for project debt and even higher levels (10 to 30) for debt
36 finance provided on concessional terms (IFC 2021a 2021). Although AAA-rated IFC blended finance
37 fund was established in 2013, it took on seven of its eight institutional investors in 2017 with insurers
38 AXA and Swiss Re investing 500 million USD each to bring the fund to 7 billion USD raised from
39 eight global investors (Attridge and Gouett 2021). Critics of blended finance mechanisms point to lack
40 of data transparency hampering independent assessment on i) value for public money and costs of
41 blending versus other financial mechanisms ii) risks and benefits of de-risking private capital to
42 collateralising climate vulnerable Global South populations iii) lack of partnership with local players
43 iv) complex structures (Akyüz 2017; Mawdsley 2018; Convergence 2020; Daniela Gabor 2021;
44 Attridge and Gouett 2021). Whilst blended finance transactions (BFTF 2018) are quite common in
45 mature regulated markets with mandatory reporting requirements (Morse 2015; ICAEW 2021), the
46 additional finance mobilised and their developmental impact remain unknown due to poor reporting
47 that hampers evidence-based policy making (Attridge and Gouett 2021). Projects that are aligned with
48 blended finance principles in the UN Addis Agenda (UN 2015a) and take account of local contexts by
49 involving local actors are much more likely to have sustainable impacts.

1 **De-risking tools to lower capital costs and mobilise diverse investors.** Paris aligned NDCs that
2 integrate policies on COVID-19 pandemic recovery, climate action, sustainable development, just
3 transition and equity can harness co-benefits including contribution to “*Invisible UN SDG 7 energy*
4 *poverty sectors*” (*high confidence*). Developing countries require access to affordable finance for
5 projects ranging from clean cooking solutions (Accenture 2018; World Bank et al. 2021); decentralised
6 energy systems, intra-country power stations and regionally shared power pools with their associated
7 energy distribution networks (IEA 2020d; IRENA 2020c). Close to 3 billion people in Africa and
8 developing Asia have no access to clean cooking. For sub-Saharan Africa, the acute lack of electricity
9 access lags behind all regions on SDG 7 indicators impacting mostly women and children (see Chapter
10 6, box 6.1; (IEA et al. 2021; IEA 2021e; Stritzke et al. 2021; Zhang 2021)). These dire statistics remind
11 of compounding tensions: Historical inequities and the associated “first comer” exploiting Africa
12 resources for development elsewhere, the local climate change, “latecomer” capacity development and
13 technology transfer challenges, illicit mining finance and stranded assets (UNU-INRA 2019; Bos and
14 Gupta 2019; War on Want 2016; Arezki 2021). The COVID-19 pandemic exacerbates this tension with
15 more people pushed below the poverty line (Sumner et al. 2020) (see Box 15.6). Recent analysis points
16 to the 60 largest banks providing 3.8 trillion USD to fossil fuel companies since 2016, including inside
17 Africa (Rainforest Action Network et al. 2021). IMF estimated fossil fuel subsidies totalling 5.2 trillion
18 USD or 6.5% of global GDP in 2017 (Coady et al. 2019) to be compared with the 2.4 trillion USD yr⁻¹
19 energy investments over the next decade to limit global warming to 1.5°C (IPCC 2018). Analysts point
20 to models in improvements to resources husbandry that include i) minerals strong governance SWFs
21 for domestic development (Wills et al. 2016) and ii) compensation for Africa (Walsh et al. 2021) leaving
22 fossil fuels underground (McGlade and Ekins 2015) in the *Just Transition* (section 15.2.4) and *Right to*
23 *Develop* debates as assets continue to be mined (IEA 2019c). In many developing regions, some of the
24 world’s best renewable energy sources remain out of reach due to high costs which can be up to seven
25 times that in developed countries (IEA 2021a). Shifting some risks through financial de-risking
26 approaches could be instrumental (Schmidt 2014; Sweerts et al. 2019; Drumheller et al. 2020; Matthäus
27 and Mehling 2020) .

28 **Combining approaches: i) developed countries meeting UNFCCC 100 billion USD commitment**
29 **on a grant-equivalent basis ii) stepped up technical assistance iii) infrastructure co-ordination iv)**
30 **knowledge sharing by project preparation entities iv) harnessing project risk facilities such as**
31 **guarantees could be instrumental for scaling climate finance for Paris-SDGs** (*high confidence*).
32 Figure 15.7 illustrates the interplay between infrastructure project financing phases, bond refinancing
33 and opportunities for developing bond yield curve benchmarks in nurturing local capital markets and
34 mobilising diverse investors. These project financing phases have varying risk-return profiles and
35 different benchmarks to track performance are needed by investors for different types of securities that
36 might be created (Ketterer 2014; Ketterer and Powell 2018).

37

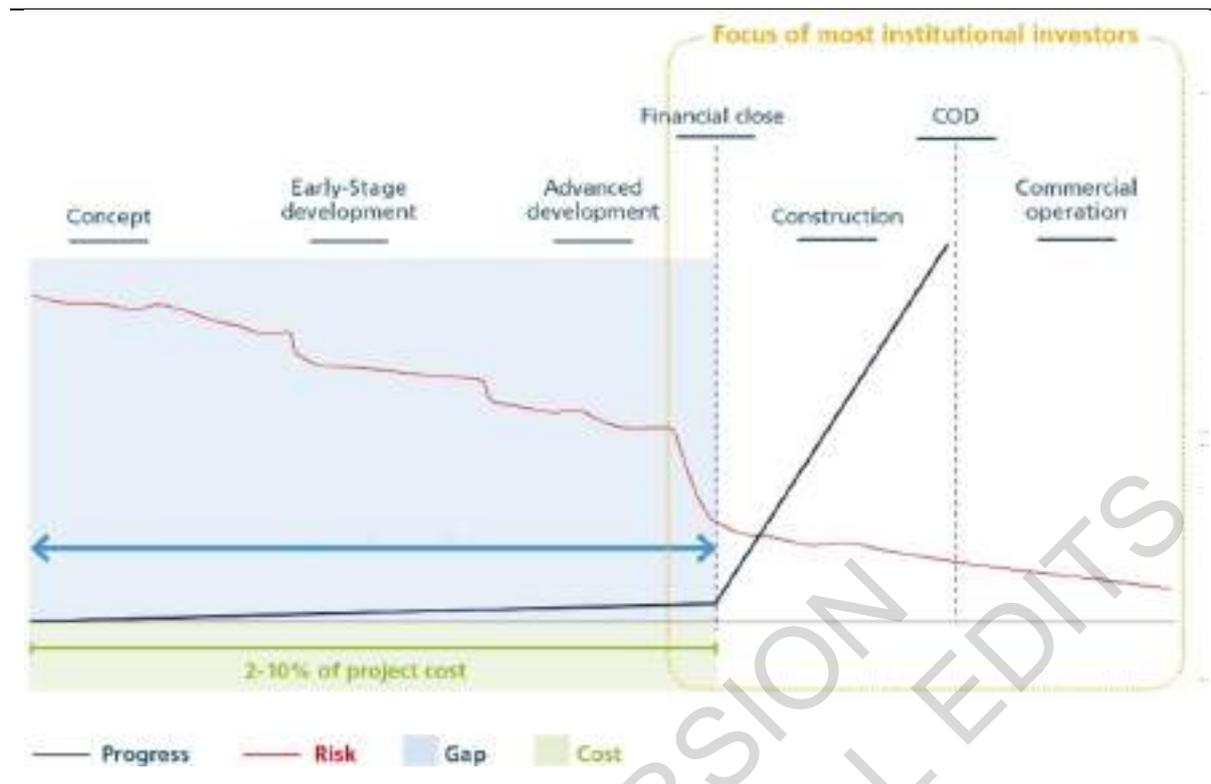

Figure 15.7 Bond refinancing mobilises institutional investors in mature project phase. De-risk early stage infrastructure projects. Source: Building on PIDG 2019

1 A (ODI 2018) survey of private and public project preparation facilities internationally, showed high
 2 failure rates in *early project preparation phases* with recommendations on “one-stop-shops” and
 3 knowledge sharing on effective approaches. During the very high-risk *concept phase* (Figure 15.7) –
 4 grants and technical assistance de-risk with design concepts, project proposals and feasibility studies
 5 completed to “kick-start” the right projects. The early stage developmental phase is characterised by
 6 short-term debt in the 2-5 year phase to complete construction enabled by concession finance. Bank
 7 loans are paid back by issuing bonds once the construction phase is completed. Such bond refinancing
 8 over say 15-25 years, in the *low risk mature project phase* can provide a lower cost of capital. Market-
 9 making to develop a pipeline of investment opportunities uses a complimentary mix of high-risk capital
 10 options in the form of grants, guarantees, equity, mezzanine financing that can help (Attridge and Gouett
 11 2021) i) reduce up-front risks in the early phases ii) allow banks to recycle loans to new projects iii)
 12 galvanise multilateral technical assistance for building bond yield curve benchmarks and de-risking
 13 local currency bond issuance of long tenors such as green bonds/resilience bonds (Berensmann et al.
 14 2015; CBI 2015; Mercer 2018; Dasgupta et al. 2019; PIDG 2019; Braga et al. 2021; CBI et al. 2021;
 15 Hourcade et al. 2021a,b) . Convergence 2019 points to investment from commercial banks with
 16 commercial debt of 11-15years maturity being covered by guarantees. To achieve scale, some have
 17 issued SPV green infrastructure project bonds combining tenors up to 15 years with credit ratings
 18 assigned to mobilise investors with community trusts for local participation (Mathews and Kidney
 19 2012; Kaminker and Stewart 2012; Mbeng Mezui and Hundal 2013; Essers et al. 2016; Moody’s
 20 Investors Service 2016; Ng and Tao 2016; Harber 2017). Bond refinancing could be facilitated through
 21 standardised national infrastructure style bonds, national infrastructure funds (Amony 2009; Ketterer
 22 and Powell 2018) and country SPV infrastructure funds issuing bonds (Cavallo and Powell 2019)
 23 embedding MDBs.

1 **Existing project risk facilities including guarantees could benefit from co-ordination, scaling and**
2 **better reporting frameworks** (high confidence). Individual and clubs of developed and developing
3 countries currently provide public guarantees (ADB 2015; IIGCC 2015; Pereira Dos Santos 2018;
4 GGGI 2019; PIDG 2019; AGF 2020; Garbacz et al. 2021). However MDB business model imposes
5 limitations on use of guarantees and collaboration with other MDBs (Gropp et al. 2014; Schiff and
6 Dithrich 2017; Lee et al. 2018; Pereira dos Santos and Kearney 2018b). Loans continue to dominate as
7 the financial instrument of choice by MDBs and DFIs, with guarantees mobilising the most private
8 finance for OECD reported data even if their use remains limited (IATFD 2020; OECD 2020c; Attridge
9 and Gouett 2021). Ramping up the use of guarantees to mobilise private investment raises questions
10 around understanding efficacy in the design as there is no one size that fits all and more research is
11 required to better understand this aspect (Convergence 2019). Sample guarantee forms in literature: i)
12 single country Sweden and USA DFI forms (SIDA 2016, DCA 2018) ii) multilateral institution
13 offerings (Pereira Dos Santos 2018; IRENA 2020e) iii) multi-sovereign guarantees one-stop platforms
14 such as those on the PIDG/Guarantco (PIDG 2019) and Africa Guarantee Fund owned by DFIs,
15 including AfDB, AFD, NDF, and KfW (AGF 2020) iv) MIGA, established to provide political risk
16 guarantees (enhanced green MIGA) (Déau and Touati 2018) v) multilateral partnerships with
17 developing nations via infrastructure funds (see 15.6.7.2) and green infrastructure options (de Gouvello
18 and Zelenko 2010; Studart and Gallagher 2015) vi) guarantees embedded in project risk facilities such
19 as currency fund TCX established by 22 DFIs (TCX 2020) and vii) ASEAN and African multi-
20 sovereign regional local currency bond guarantee funds and a co-guarantee platform (GGGI 2019;
21 Garbacz et al. 2021). Fossil fuels currently benefit from de-risking tools from export credit agencies
22 (Lawrence and Archer 2021) with questions around sustainable development (Wright 2011)); (Gupta
23 et al. 2020) argue that these could be deployed for renewable energy. C40 Cities Facility; Blue Natural
24 Capital Facility (IUCN 2021); Clean Cooking Fund (ESMAP 2021) and opportunities for guarantees in
25 LDCs (Garbacz et al. 2021). World Bank's Renewables Risk Mitigation (GCF 2021), World Bank's
26 Global Infrastructure Facility. UNEP Seed Capital are sample project facilities across diverse project
27 types (GGGI 2019). Multilaterals offer credit enhancement to manage both actual and perceived risks:
28 in the India corporate sector, renewable energy SPV project bonds have been guaranteed jointly by
29 ADB and an infrastructure company raising the credit rating from sub-investment grade to investment
30 grade to lower borrowing costs (ADB 2018; Agarwal and Singh 2018; Carrasco 2018).

31 Investment vehicles into green infrastructure come in various forms (*high confidence*) and can include
32 indirect corporate investment such as bonds; semi-direct investment funds via pooled vehicles such
33 infrastructure funds and private equity funds and project investment (direct) in green projects through
34 equity and debt including loan, project bonds and green bonds. Pension funds in Australia and Canada
35 direct investment in infrastructure is about 5% of total AUM (Inderst and Della Croce 2013) whilst less
36 than 1% for OECD pension funds go to green infrastructure (Kaminker et al. 2013). Some regional
37 developing country institutional investors use a variety of investment vehicles that span SPVs, private
38 equity, domestic and regional local currency bond markets with statutory level mandates to address
39 historic inequities (GEPF 2019). Cross-border collaboration in regional power markets such as Europe's
40 Nordpool; for developing countries could be led by technical partnership from infrastructure funds and
41 multilaterals (Oseni and Pollitt 2016; Juvonen et al. 2019; Chen et al. 2020; Nordpool 2021). Barriers
42 to investments include non-standardised investment vehicles of scale and lack of national infrastructure
43 road maps to give investor confidence in government commitment. Some have set up infrastructure co-
44 ordinating entities embedding local science and engineering R&D (IPA 2021; National Infrastructure
45 Commission (NIC) 2021). (Arezki et al. 2016) argue that co-ordination within existing platforms could
46 create a global infrastructure investment platform for de-risking through guarantees and securitization;
47 (Matthäus and Mehling 2020) point to a global guarantee mechanism. Such multilateral approaches
48 create credibility enhancing effects in developing capital markets. (Hourcade et al. 2021a) suggest that
49 the overall economic efficiency could be higher with guarantees calibrated per ton on an agreed "*social,*
50 *economic, and environmental value of mitigation actions [and] their co-benefits*" (Article 108, Paris

1 Agreement) which would operate as a notional carbon price (High-Level Commission on Carbon Prices
2 2017). The grant equivalent of guarantees and induced equity inflows could be far beyond the US 100
3 billion promise. Such cooperative solutions in adopting development of local capital markets would end
4 the drawbacks of the current plethora of low-scale fragmented project-by-project and ‘special-purpose’
5 pilots and programs.

6 **Harnessing existing bond markets and securities exchanges in nascent markets.** The G20 has an
7 action plan to support strengthening local currency bond markets and development of local capital
8 markets is also part of the option for financing UN SDGs in developing countries (UN 2015a) 2015;
9 UN 2019, 2020; IATFD 2016; UN IATFD 2021). Primers are available on bond market development
10 to support policy choices (World Bank and IMF 2001; Silva et al. 2020; World Bank 2020; Adrian et
11 al 2021; IMF and World Bank 2021). Developing government bond yield curves with different
12 maturities can be an important policy objective (*high confidence*). This can support pricing discovery,
13 liquidity (Wooldridge 2001) and can be achieved through step by step tranches from shorter to longer
14 maturities to boost confidence and encourage municipals and other quasi-sovereigns. Money market
15 instruments (such as, green commercial paper) anchor the short end of the yield curve with bonds of
16 varying maturity issued by sovereign/quasi-sovereign entities (national treasuries, SOEs,
17 municipalities) to mobilise investors (Goodfriend 2011; LSEG 2018; Tolliver et al. 2019). A variety
18 of bonds are being used for developing countries including green (Ketterer et al. 2019), blue-water (Roth
19 et al. 2019), transition, SDG/social, biodiversity bonds (Aglionby 2019), green/resilience bonds (AAC
20 2021); gender bonds (Andrade and Prado 2020); diaspora (LSEG 2017) and infrastructure project
21 bonds (CBK 2021). Local policy-makers would gain from technical and financial assistance in building
22 green yield curves, for example with support from multilaterals (EIB 2012; IATFD 2016; Shi 2017;
23 EIB 2018). Green bonds are one of the most readily accessible to help fund Paris goals (Tolliver et al.
24 2019; Tuhkanen and Vulturius 2020). Section 15.3.2 refers to the growth in labelled bond markets (CBI
25 2021b), low borrowing costs and yield curve building in Europe (Bahceli 2020; Serenelli 2021;
26 Stubbington 2021; HM Treasury and UK DMO 2021). For developing countries, labelled bonds have
27 mostly been in hard currency (e.g. (Smith 2021)) despite local currency markets making up more than
28 80 percent total debt stock (IMF and World Bank 2016; Silva et al. 2020; Adrian et al 2021; Inderst
29 2021). The labelled bonds issuance by multilaterals do not currently mobilise the trillion levels needed.
30 Research studies show that participating in green bond markets in part depends on a country having
31 credible NDCs (Tolliver et al. 2020a,b) and highlights diverse approaches working together to support
32 local bond market development (Amacker and Donovan 2021; ICMA 2021; IMF and World Bank 2021)

33 **Technical assistance options would benefit from co-ordination. Labelled bond costs remain high.**
34 **Developing countries are using fiscal incentives, grants, and guarantees to support nascent bond**
35 **markets with most taxonomies under development** (*high confidence*). Technical assistance
36 requirements to improve the investment climate and bond market development will vary across national
37 capacities. These would benefit from the 100 billion USD UNFCCC grant equivalent basis to develop
38 i) regulatory and policy frameworks ii) UN national statistical systems (Singh et al. 2016; MacFeely
39 and Barnat 2017; Paris21 2018; Bleeker and Abdulkadri 2020);iii) credible NDC and SDG investment
40 plans iv) project assessment certification and taxonomies v) bond market guidelines vi) public finance
41 management (US DoJ 2019, 2009). Other technical assistance channels include diaspora entities,
42 universities and learned societies (ICEAW 2012; Mahmud and Huq 2018; UNFCCC 2021). LDCs are
43 least likely to have active capital markets. Clubs of LDCs are partnering with AAA MDBs in
44 aggregation approaches (AfDB 2020; GCF 2020b). Some UN entities provide technical assistance on
45 municipal aggregation of projects (UN CDF 2020) with Africa, LDC, SIDS nations and cities accessing
46 green technical facilities and listings for labelled bonds (C40 Cities Climate Leadership Group 2016;
47 Gorelick 2018; Jackson 2019; FSD Africa and CBI 2020; Gorelick and Walmsley 2020; MoE Fiji 2020
48 2020; IFC 2021). Elevated climate risks imperil developing country ability to repay debts (Schmidt
49 2014; Buhr et al. 2018; Volz et al. 2020; Dibley et al. 2021). To lower overall costs and achieve more -
50 entities have accessed technical assistance, listed local currency labelled bonds, used credit enhancing

1 bond guarantees, regulatory treatments and philanthropy schemes (Europe 2020 Project Bond Initiative
2 2012; SBN 2018; Agliardi and Agliardi 2019; Banga 2019). In the regions, China issued guidelines for
3 stock exchanges and regulatory support for green bonds (Cao and Ma 2021), India issued regulations
4 for local issuance of green bonds (CBI 2019a) while in the LAC region; both plain vanilla and labelled
5 bonds use the same authority (Ketterer et al. 2019). Africa, LDC and SIDS nations are reviewing ways
6 to harness local exchanges (SSE 2018; GCF 2019; ASEAN et al 2021; UN CDF 2021b). For taxonomies,
7 the differences reflect the multitude of local Just Transition pathways, some with purely environmental
8 focus and others incorporating livelihood improvements (ICMA 2021). The sustainable bond market
9 has been expanding as transition bonds become listed in anticipation of future developments (Roos
10 2021).

11 **Progress towards transparency using scientific-based methods to build trust and accountability.**

12 After 60 years of development finance, critics underline limits coming from i) lack of aid and debt
13 transparency (Moyo 2009; Mkandawire 2010; PWYF 2020) ii) mining-fossil fuels sector and illicit
14 finance (Plank 1993; Sachs and Warner 2001; Hanlon 2017b)) iii) lack of developed country
15 commitment to pledges (Nhamo and Nhamo 2016) iv) unregulated players as financial intermediaries
16 in blended finance (Pereira 2017; Donaldson and Hawkes 2018; Tan 2019) v) weak accountability
17 reflected in soft SDG data measurement and vi) burden of responsibility in mobilising resources for
18 Paris and SDG to countries with historically soft institutional capacity (Hickel 2015; Donald and Way
19 2016; Scheyvens et al. 2016; Liverman 2018). Literature around trust in blended finance pinpoints four
20 progress areas in accountability. First, debt transparency through public debt registries, centralised UN
21 legacy debt restructuring and science-centred UN national statistical systems (Donaldson and Hawkes
22 2018; Jubilee Debt Campaign 2019; Stiglitz and Rashid 2020). Second, international reporting bell-
23 weathers could be called upon to produce harmonized mandatory reporting frameworks that capitalize
24 on TCFD to capture climate, debt sustainability (see 15.6.7.3), SDG and fossil fuel (GISD 2020); third,
25 standardization of assessment by third parties of the quantity and values of carbon saved by green
26 projects (Hourcade et al. 2012) and of their contribution to quantified performance biodiversity targets
27 (FfB 2021) to facilitate their bundling, securitization and repackaging in standardized liquid products
28 and bonds (Arezki et al. 2016; Blended Finance Taskforce 2018a).

29

30 **15.6.8 Facilitating the development of new business models and financing approaches**

31 New and innovative business models and financing approaches have emerged to help overcome barriers
32 related to transactions costs by aggregating and/or transferring financing needs and establishing supply
33 of finance for stakeholder groups lacking financial inclusion (*high confidence*).

34 **15.6.8.1 Service-based business models in the energy and transport sectors**

35 **Energy-as-a-service (EaaS)** is a business model whereby customers pay for an energy service without
36 having to make any upfront capital investment (PWC 2014; Hamwi and Lizarralde 2017; Cleary and
37 Palmer 2019). EaaS performance-based contracts can also be a form of “creative financing” for capital
38 improvement that makes it possible to fund energy upgrades from cost reductions and deployment of
39 decentralised renewable energy (KPMG 2015; Moles-Grueso et al. 2021). Innovation in EaaS has
40 started at the household level, where smart meters using real-time data are used to predict peak demand
41 levels and optimise electricity dispatch (Chasin et al. 2020)(Government of UK 2016) (Smart Energy
42 International 2018).

43 **Aggregators.** An aggregator is a grouping of agents in a power system to act as a single entity when
44 engaging in power system markets (MIT 2016). Aggregators can use operation optimisation platforms
45 to provide real-time operating reserve capacity and a range of balancing services to integrate higher
46 shares of variable renewable energy (VRE) (Zancanella et al. 2016)(Ma et al. 2017; Enbala 2018;
47 Research and Markets 2017; IRENA 2019b). This makes a business case for deferred investments in

1 grid infrastructure (*medium confidence*). Aggregating and managing demand-response of heat systems
2 (micro CHP and heat pumps) has shown reduction in peak demand (TNO 2016).

3 **Peer-to-peer (P2P) electricity trading.** Producers and consumers can directly trade electricity with
4 other consumers in an online marketplace to avoid the relatively high tariffs and the relatively low buy-
5 back rates of traditional utilities (IRENA 2020f; Liu et al. 2019). P2P models trading with distributed
6 energy resources reduce transmission losses and congestion (Mengelkamp et al. 2018; SEDA 2020;
7 Lumenaza 2020; Sonnen 2020; UNFCCC 2020).

8 **Community-ownership models.** Community-ownership models refer to the collective ownership and
9 management of energy-related assets with lower levels of investment, usually distributed renewable
10 energy resources but also recently in heating systems and energy services (e.g. storage and charging)
11 (Gall 2018; IRENA 2018; Kelly and Hanna 2019; Singh et al. 2019; Bisello et al. 2021; Maclurcan and
12 Hinton 2021). Community-ownership projects may need significant upfront investments, and the ability
13 of communities to raise the required financing might prove insufficient, which can be supported by
14 microcredits in the initial stages of the projects (Aitken 2013; Federici 2014; REN21 2016; Rescoop
15 2020).

16 **Payment method: Pay-as-you-go (PayGo).** PayGo business models emerged to address the energy
17 access challenge and provide chiefly solar energy at affordable prices, using mobile telecommunication
18 to facilitate payment through instalments (IRENA 2019c) (Yadav et al. 2019). However, PayGo has the
19 technology and product risk, requires a financially viable and large customer base, and the system
20 supplier must provide a significant portion of the finance and requires substantial equity and working
21 capital (C40 Cities Climate Leadership Group 2018).

22 **Transport sector business models.** Analog to EaaS, Mobility-as-a-Service (MaaS) offers a business
23 model whereby customers pay for a mobility service without making any upfront capital investment
24 (e.g., buying a car). MaaS tends to deliver significant urban benefits (e.g., cleaner air) and brings in
25 efficiency gains in the use of resources (*high confidence*). However, the switch to MaaS hardly improves
26 the carbon footprint and further tempted on-demand mobility is likely to nurture carbon emissions
27 (Suatmadi et al. 2019). Therefore, to support climate change mitigation, MaaS must be integrated with
28 the deployment of smart charging of electric (autonomous) vehicles coupled to renewable energy
29 sources (IRENA 2019d)(Jones and Leibowicz 2019).

30 **Financial technology applications to climate change.** Financial technology abbreviated as 'fintech'
31 applies to data-driven technological solutions that aims to improve financial services (Schueffel 2018;
32 Dorfleitner et al. 2017; Lee and Shin 2018). Fintech can enhance climate investment in innovative
33 financial products and build trust through data, but also presents some challenges including related to
34 potentially significant emissions from increased energy use with distributed transactions (Lei et al.
35 2021). Blockchain is a key fintech that secures individual transactions in a distributed system, which
36 can have many applications with high impact potential but is also associated with uncertainty (OECD
37 2019c; World Energy Council 2019). Fintech applications with climate change mitigation potential
38 have been growing recently, including tracking payment or asset history for credit scoring in AFOLU
39 activities (Nassiry 2018; Davidovic et al. 2019), blockchain supported grid transactions (Livingston et
40 al. 2018), carbon accounting throughout value chains (World Bank 2018b), or transparency and
41 verification mechanisms for green financial instrument investors (Kyriakou et al. 2017; Stockholm
42 Green Digital Finance 2017). Generally, blockchain and digital currency applications are not well
43 covered by governance systems (Tapscott and Kirkland 2016; Nassiry 2018), which could lead to
44 problems with security (Davidovic et al. 2019), and some licensing and prudential supervision
45 frameworks are in flux.

1 **15.6.8.2 Nature-based solutions including REDD+**

2 Nature-based solutions are ‘actions to protect, sustainably manage and restore natural or modified
3 ecosystems that address societal challenges effectively and adaptively, simultaneously providing human
4 well-being and biodiversity benefits (Cohen-Shacham et al. 2016)’. Nature-based solutions consist of a
5 wide range of measures including ecosystem-based mitigation and adaptation.

6 The studies on the investment and finance for the nature-based solutions is still limited. However,
7 framework and schemes to incentivise the implementation of nature-based solutions, such as reducing
8 emissions from deforestation and forest degradation and the role of conservation, sustainable
9 management of forests and enhancement of forest carbon stocks in developing countries (REDD+),
10 which contributes to the climate change mitigation has been actively discussed under the UNFCCC,
11 with lessons from finance for REDD+ being available.

12 If effectively implemented, nature-based solutions can be cost-effective measures and able to provide
13 multiple benefits, such as enhanced climate resilience, enhanced climate change mitigation, biodiversity
14 habitat, water filtration, soil health, and amenity values (Griscom et al. 2017; Keesstra et al. 2018;
15 OECD 2019d; Griscom et al. 2020; Dasgupta 2021) (*high confidence*).

16 The nature-based solutions have large potential to address climate change and other sustainable
17 development issues (*high confidence*). Nature-based solutions are undercapitalised and the limited
18 investment and finance, especially limited private capital is widely recognised as one of the main
19 barriers to the implementation and monitoring of the nature-based solutions (Seddon et al. 2020;
20 Toxopeus and Polzin 2021; UNEP et al. 2021) Finance and investment models that generates its own
21 revenues or consistently saves costs are necessary to reduce dependency on grants (Schäfer et al. 2019;
22 Wamsler et al. 2020).

23 **REDD+**. REDD+, can significantly contribute to climate change mitigation and also produce other co-
24 benefits like climate change adaptation, biodiversity conservation, and poverty reduction, if well-
25 implemented (Milbank et al. 2018; Morita and Matsumoto 2018) (*high confidence*). We use the term
26 REDD+ broadly, not limited to REDD+ implemented under the UNFCCC decisions, including Warsaw
27 Framework for REDD+ (see Chapter 14), but include voluntary REDD+ projects, such as projects
28 which utilise voluntary carbon markets. Finance is a core element that incentivise and implement
29 REDD+ activities. Various financial sources are financing REDD+ activities, including bilateral and
30 multilateral, public and private, and international and domestic sources, with linking with several
31 finance approaches/mechanisms including results-based finance and voluntary carbon markets (FAO
32 2018). However, there is lack of sufficient finance for REDD+ (Lujan and Silva-Chávez 2018; Maguire
33 et al. 2021). REDD+ under the UNFCCC are implemented in three phases, readiness, implementation,
34 and results-based payment phases. The Ecosystem Marketplace identified that at least USD 5.4 billion
35 in REDD+ in three phases funding committed through multiple development finance institutions so far
36 (Maguire et al. 2021), and public funds are main sources that are supporting three phases, and most of
37 the REDD+ finance were spent to the readiness phase (Atmadja et al. 2018; Lujan and Silva-Chávez
38 2018; Watson and Schalatek 2021). There is significant gap between the existing finance and finance
39 needs of REDD+ in each phase (Lujan and Silva-Chávez 2018). Furthermore, private sector
40 contribution to REDD+ is currently limited mostly to the project-scale payments for carbon offsets/units
41 through voluntary carbon market (McFarland 2015; Lujan and Silva-Chávez 2018).

42 Current main challenges of REDD+ finance include the uncertainty of compliance carbon markets
43 (which allow regulated entities to obtain and surrender emissions allowances or offsets to meet
44 regulatory emissions reduction targets) (Maguire et al. 2021), as well as limited engagement of private
45 sector in REDD+ finance (*high confidence*). With regard to the compliance carbon markets, at the
46 international level, integrating climate cooperation through carbon markets into Article 6 of the Paris
47 Agreement and including REDD+ has potential to enable emission reduction in more cost-effective
48 way, while the links between carbon markets and REDD+ under the Article 6 is under discussion at the

1 UNFCCC (Environmental Defense Fund 2019; Maguire et al. 2021) (see Chapter 14). At the national
2 and subnational levels, although compliance carbon markets such as in New Zealand, Australia and
3 Colombia allow forest carbon units, how REDD+ will be dealt in the national and subnational
4 government- led compliance carbon markets are uncertain (Streck 2020; Maguire et al. 2021). As for
5 limited engagement of private sector in REDD+ finance, there are various reasons why mobilising more
6 private finance in REDD+ is difficult (Dixon and Challies 2015; Laing et al. 2016; Golub et al. 2018;
7 Ehara et al. 2019; Streck 2020). The challenges include the needs of a clear understanding of carbon
8 rights and transparent regulation on who can benefit from national REDD+ (Streck 2020); a clear
9 regulatory framework and market certainty (Dixon and Challies 2015; Laing et al. 2016; Golub et al.
10 2018; Ehara et al. 2019); strong forest governance (Streck 2020), and implementation of REDD+
11 activities in different levels, national and subnational levels. Other challenges are associated with the
12 nature of forest-based mitigation activities, the costs and complexity for monitoring, reporting and
13 verification of REDD+ activities, because of the need to consider the risks of permanence, carbon
14 leakage, and precisely determine and monitor the forest carbon sinks (van der Gaast et al. 2018; Yanai
15 et al. 2020). Although REDD+ has many challenges to mobilise more private finance, there is discussion
16 on exploring other finance opportunities for forest sector, such as building new blended finance models
17 combining different funding sources like public and private finance (Streck 2016; Rode et al. 2019),
18 and developing enhanced bonds for forest-based mitigation activities (World Bank 2017).

19 **Private finance opportunities for nature-based solutions.** The development of nature-based solutions
20 face barriers that relate to the value proposition, value delivery and value capture of nature-based
21 solutions business models and sustainable sources of public/private finance to tap into (Toxopeus and
22 Polzin 2017; Mok et al. 2021) (*high confidence*). However, the demand of establishing new finance and
23 business models to attract both public and private finance to nature-based solutions is increasing in a
24 wide range of topics such as urban areas, forestry and agriculture sectors, and blue natural capital
25 including mangroves and coral reefs (Toxopeus and Polzin 2017; EIB 2019; Cziesielski et al. 2021;
26 Mok et al. 2021; Thiele et al. 2021; UNEP et al. 2021) Furthermore, the recognition of the needs of
27 financial institutions to identify the physical, transition and reputational risks resulting from not only
28 the climate change but also loss of biodiversity is gradually increasing (De Nederlandsche Bank and
29 PBL Netherlands Environmental Assessment Agency 2020; Dasgupta 2021; TNFD 2021).
30 Development of finance and business models for nature-based solutions need to be explored, for
31 example through utilizing a wide range of financial instruments (e.g. equity, loans, bonds, and
32 insurance), and creating standard metrics, baselines and common characteristics for nature-based
33 solutions to promote the creation of a new asset class (Thiele et al. 2021; UNEP et al. 2021).

34 **15.6.8.3 Exploring gender-responsive climate finance**

35 Global and national recognition of the lack of finance for women has led to increasing emphasis on
36 financial inclusion for women (*high confidence*). Currently, it is estimated that 980 million women are
37 excluded from formal financial system (Miles and Wiedmaier-Pfister 2018); and there is a 9% gender
38 gap in financial access across developing countries (Demirguc-Kunt et al. 2018). This gender gap is the
39 percent of men and women with bank accounts as measured and reported in the Global Financial
40 Inclusion (Global Findex) database. Policies and framework to expand and enhance financial inclusion
41 also extend to the area of climate finance (*high confidence*). Since AR5, there remains many questions
42 and not enough evidence on the gender, distribution and allocative effectiveness of climate finance in
43 the context of gender equality and women's empowerment (Williams 2015a; Chan et al. 2018; Wong
44 et al. 2019). Nonetheless, the existing global policy framework (entry points, policy priorities etc.) of
45 climate funds is gradually improving in order to support women's financial inclusion in both the public
46 and the private dimensions of climate finance/investment (Schalatek 2015; Chan et al. 2018; Schalatek
47 2020). At the level of public multilateral climate funds, there have been significant improvements in
48 integrating gender equality and women's empowerment issues in the governance structures, policies,
49 project approval and implementation processes of existing multilateral climate funds such as the
50 UNFCCC's funds managed by the Global Environment Facility, the Green Climate Fund and the World

1 Bank's CIFs (Schalatek 2015; Williams 2015a; GGCA 2016; GCF 2017) (*high confidence*). But
2 according to a recent evaluation report, the integration of gender into operational policies and
3 programme is fragmented and there is lack of an 'adequate, systematic and comprehensive gender
4 equality approach for the allocation and distribution of funds for projects and programmes on the
5 ground' (GEF Independent Evaluation Office 2017; Schalatek 2018). The review found that 'almost
6 half of the analysed sample of 70 climate projects were judged to be largely gender-blind, and only 5%
7 considered to have successfully mainstreamed gender, including in two Least Developed Countries
8 Fund adaptation projects' (GEF Independent Evaluation Office 2017; Schalatek 2018). While the GCF
9 requires funding proposals to consider gender impact as part of their investment framework⁷, the fund
10 does not have its own funding stream targeted to women's project on the ground, nor is there as yet an
11 evaluation as to how entities are actually implementing gender action plan in the projects. In the case
12 of the CIFs, as noted by (Schalatek 2018), 'gender is not included in the operational principles of the
13 Pilot Program on Climate Resilience (PPCR), which funds programmatic adaptation portfolios in a few
14 developing countries, although most pilot countries have included some gender dimensions'. And,
15 'gender is not integrated into the operations of the Clean Technology Fund (CTF), which finances large-
16 scale mitigation in large economies and accounts for 70% of the CIFs pledged funding portfolio of 8.2
17 billion USD' (Schalatek 2018). However, both the Forest Investment Program (FIP) and the Scaling-
18 Up Renewable Energy in Low-Income Countries Program (SREP) have integrated gender equality as
19 either a co-benefit or core criteria of these programmes (Schalatek 2018).

20 Overall, efforts to promote gender responsive/sensitive climate finance, at national and local levels,
21 both in the public and private dimensions and more specifically in mitigation-oriented sectors such as
22 clean and renewable energy remains deficient (*high confidence*). Recent developments in the capital
23 markets in the areas of social bond are focused around gender bonds -- debt instruments targeted to
24 activities and behaviours that are relevant to gender equality and women's empowerment. These bonds
25 are aligned with Sustainability-linked Bonds as well as Social Bonds Principles of the International
26 Capital Market Association. Issuances of gender-labelled bonds are increasing in the Asia Pacific region
27 (the most comprehensive initiative is the Impact Investment Exchange's (IIX) multi-country USD150
28 million Women's Livelihood Bond⁸) and in Latin America, Columbia, Mexico and Panama each have
29 gender bond issuances). Additionally, a few developing countries, such as Pakistan (May 2021) and
30 Morocco (March 2021) have issued gender bond guidelines for financial market participants.

31 **Linkage to sectoral climate change issues and gender and climate finance.** Subsets of actions
32 designed to enhance women's more formal integration into climate policies, programmes and actions
33 by the global private sector include: investment in clean energy, redirecting funds to support women
34 and vulnerable region as a component of social and green bonds as well as insurance for climate risk
35 management. In the latter context, insurance providers are arguing that 'given the fact that women are
36 disproportionately affected by climate change, there could be new finance innovations to address this
37 gap.' AXA and IFC estimate that the global women's insurance market has the opportunity to grow to
38 three times its current size, to 1.7 trillion USD by 2030 (AXA Group et al. 2015; GIZ et al. 2017).
39 However, across the board and in particular with regard to public funds, despite improvements in the
40 substantive gender sensitization and operational gender responsiveness of multilateral and bilateral
41 climate finance funds operations, current flows of public and climate finance do not seem to be going

FOOTNOTE⁷ Notably, the GCF provides guidance to Accredited Entities submitting funding proposals on the inclusion of an initial gender and social assessment during the project planning, preparation and development stage and a gender and social inclusion action plan at the project preparation stage.

FOOTNOTE⁸ The WLB series has been on the market since 2017 when WLB1 was launched. WLB2 issuance of \$12 million arrived January 2020. WLB 3 was launched December 2020 to support 180,000 underserved women and women entrepreneurs in the Asia Pacific to respond, to recover from, and to build resilience in the aftermath of the COVID-19 pandemic. See (IIX 2020) and (Rockefeller Foundation and Shujog 2016).

1 to women and the local communities in significant amounts (Chan et al. 2018; Schalatek 2020). At the
2 same time, evaluations of the effectiveness of climate finance show that equitable flow of climate
3 finance can play an important role in levelling the playing field and in enabling women and men to
4 successful respond to climate change and to enable the success and sustainability of local response in
5 ensuring effective and sustainable climate strategies that can contribute to the global goals of the Paris
6 Agreement (Minniti and Naudé 2010; Bird et al. 2013; Barrett 2014; Eastin 2018). This is particularly,
7 so in the case of female-owned MSMEs, who, the literature increasingly show, are key to promoting
8 resilience at micro and macro scale in many developing countries (Omolo et al. 2017; Atela et al. 2018;
9 Crick, F. et al. 2018).

12 **Frequently Asked Questions**

13 **FAQ 15.1 What's the role of climate finance and the finance sector for a transformation towards** 14 **a sustainable future?**

15 The Paris Agreement has widened the scope of all financial flows from climate finance only to the full
16 alignment of finance flows with the long-term goals of the Paris Agreement. While climate finance
17 relates historically to the financial support of developed countries to developing countries, the Paris
18 Agreement and its Article 2.1(c) has developed on a new narrative on that goes much beyond traditional
19 flows and relates to all sectors and actors. Finance flows are consistent when the effects are either
20 neutral with or without positive climate co-benefits to climate objectives; or explicitly targeted on
21 climate benefits in adaptation and/or mitigation result areas. Climate-related financial risk is still
22 massively underestimated by financial institutions, financial decision-makers more generally and also
23 among public sector stakeholders limiting the sector's potential of being an enabler of the transition.
24 The private sector has started to recognise climate-related risks and consequently redirect investment
25 flows. Dynamics vary across sectors and regions with the financial sector being an enabler of transitions
26 in only some selected (sub-)sectors and regions. Consistent, credible, timely and forward-looking
27 political leadership remains central to strengthen the financial sector as enabler.

28 **FAQ 15.2 What's the current status of global climate finance and the alignment of global financial** 29 **flows with the Paris Agreement?**

30 There is no agreed definition of climate finance. The term 'climate finance' is applied to the financial
31 resources devoted to addressing climate change by all public and private actors from global to local
32 scales, including international financial flows to developing countries to assist them in addressing
33 climate change. Total climate finance includes all financial flows whose expected effect aims to reduce
34 net greenhouse gas (GHG) emissions and/or to enhance resilience to the impacts of current and
35 projected climate change. This includes private and public funds, domestic and international flows and
36 expenditures. Tracking of climate finance flows faces limitations, in particular for national climate
37 finance flows.

38 Progress on the alignment of financial flows with low GHG emissions pathways remains slow. Annual
39 global climate finance flows are on an upward trend since the fifth Assessment Report, according to
40 CPI reaching more than 630 billion USD in 2019/2020, however, growth has likely slowed down and
41 flows remain significantly below needs. This is driven by barriers within and outside the financial
42 sector. More than 90% of financing is allocated to mitigation activities despite the strong economic
43 rationale of adaptation action. Adjusting for higher estimates on current flows for energy efficiency
44 based on IEA data, the dominance of mitigation becomes even stronger. Persistently high levels of both
45 public and private fossil-fuel related financing as well as other misaligned flows continue to be of major
46 concern despite promising recent commitments. Significant progress has been made in the commercial
47 finance sector with regard to the awareness of climate risks resulting from inadequate financial flows
48 and climate action. However, a more consequent investment and policy decision making that enables a

1 rapid redirection of financial flows is needed. Regulatory support as a catalyser is an essential convey
2 of such redirections. Dynamics across sectors and regions vary with some being better positioned to
3 close financing gaps and to benefit from an enabling role of finance in the short-term.

4 **FAQ 15.3 What defines a financing gap, and where are the critically identified gaps?**

5 A financing gap is defined as the difference between current flows and average needs to meet the long
6 term goals of the Paris Agreement. Gaps are driven by various barriers inside (short-termism,
7 information gaps, home bias, limited visibility of future pipelines) and outside (e.g. missing pricing of
8 externalities, missing regulatory frameworks) of the financial sector. Current mitigation financing flows
9 come in significantly below average needs across all regions and sectors despite the availability of
10 sufficient capital on a global basis. Globally, yearly climate finance flows have to increase by factor
11 between 3 to 6 to meet average annual needs until 2030.

12 Gaps are in particular concerning for many developing countries with COVID-19 exacerbating the
13 macroeconomic outlook and fiscal space for governments. Also, limited institutional capacity
14 represents a key barrier for many developing countries burdening risk perceptions and access to
15 appropriately priced financing as well as limiting their ability to actively manage the transformation.
16 Existing fundamental inequities in access to finance as well as its terms and conditions, and countries
17 exposure to physical impacts of climate change overall result in a worsening outlook for a global just
18 transition.

1 **Executive summary**

2 **Innovation in climate mitigation technologies has seen enormous activity and significant**
3 **progress in recent years. Innovation has also led to, and exacerbated, trade-offs in**
4 **relation to sustainable development. (*high confidence*).** Innovation, can leverage action to
5 mitigate climate change by reinforcing other interventions. In conjunction with other enabling
6 conditions innovation can support system transitions to limit warming and help shift
7 development pathways. The currently widespread implementation of solar photovoltaic (solar
8 PV) and LEDs, for instance, could not have happened without technological innovation (*high*
9 *confidence*). Technological innovation can also bring about new and improved ways of
10 delivering services that are essential to human well-being. At the same time as delivering
11 benefits, innovation can result in trade-offs that undermine both progress on mitigation and
12 progress towards other sustainable development goals. Trade-offs include negative
13 externalities – for instance greater environmental pollution and social inequalities – rebound
14 effects leading to lower net emission reductions or even increases in emissions, and increased
15 dependency on foreign knowledge and providers (*high confidence*). Effective governance and
16 policy has the potential to avoid and minimise such misalignments (*medium evidence, high*
17 *agreement*). {16.1, 16.2, 16.3, 16.4, 16.5.1, 16.6}

18 **A systemic view of innovation to direct and organize the processes has grown over the**
19 **last decade. This systemic view of innovation takes into account the role of actors,**
20 **institutions, and their interactions and can inform how innovation systems that vary**
21 **across technologies, sectors and countries, can be strengthened (*high confidence*).** Where
22 a systemic view of innovation has been taken, it has enabled the development and
23 implementation of indicators that are better able to provide insights in innovation processes.
24 This, in turn, has enabled the analysis and strengthening of innovation systems. Traditional
25 quantitative innovation indicators mainly include R&D investments and patents. Systemic
26 indicators of innovation, however, go well beyond these approaches. They include structural
27 innovation system elements including actors and networks, as well as indicators for how
28 innovation systems function, such as access to finance, employment in relevant sectors, and
29 lobbying activities. For example, in Latin America, monitoring systemic innovation indicators
30 for the effectiveness of agroecological mitigation approaches has provided insights on the
31 appropriateness and social alignment of new technologies and practices. Climate-energy-
32 economy models, including integrated assessment models, generally employ a stylised and
33 necessarily incomplete view of innovation, and have yet to incorporate a systemic
34 representation of innovation systems {16.2, 16.2.4, 16.3, 16.3.4, 16.5, Table 16.7, Box 16.1,
35 Box 16.5}.

36 **A systemic perspective on technological change can provide insights to policymakers**
37 **supporting their selection of effective innovation policy instruments (*high confidence*).** A
38 combination of scaled-up innovation investments with demand-pull interventions can achieve
39 faster technology unit cost reductions and more rapid scale-up than either approach in isolation
40 (*high confidence*). These innovation policy instruments would nonetheless have to be tailored
41 to local development priorities, to the specific context of different countries, and to the
42 technology being supported. The timing of interventions and any trade-offs with sustainable
43 development also need to be addressed. Public R&D funding and support as well as innovation
44 procurement have shown to be valuable for fostering innovation in small to medium cleantech

1 firms. Innovation outcomes of policy instruments not necessarily aimed at innovation, such as
2 feed-in tariffs, auctions, emissions trading schemes, taxes and renewable portfolio standards,
3 vary from negligible to positive for climate change mitigation. Some specific designs of
4 environmental taxation can also result in negative distributional outcomes. Most of the
5 available literature and evidence on innovation systems come from industrialised countries and
6 larger developing countries. However, there is a growing body of evidence from developing
7 countries and small island developing states (SIDS) {16.4, 16.4.4.3, 16.4.4.4, 16.5, 16.7}.

8 **Experience and analyses show that technological change is inhibited if technological**
9 **innovation system functions are not adequately fulfilled, this inhibition occurs more often**
10 **in developing countries. (*high confidence*).** Examples of such functions are knowledge
11 development, resource mobilisation, and activities that shape the needs, requirements and
12 expectations of actors within the innovation system (guidance of the search). Capabilities play
13 a key role in these functions, the build-up of which can be enhanced by domestic measures, but
14 also by international cooperation (*high confidence*). For instance, innovation cooperation on
15 wind energy has contributed to the accelerated global spread of this technology. As another
16 example, the policy guidance by the Indian government, which also promoted development of
17 data, testing capabilities and knowledge within the private sector, has been a key determinant
18 of the success of an energy-efficiency programme for air conditioners and refrigerators in India.
19 {16.3, 16.5, 16.6, Cross-Chapter Box 12 in this chapter, Box 16.3}

20 **Consistent with innovation system approaches, the sharing of knowledge and experiences**
21 **between developed and developing countries can contribute to addressing global climate**
22 **and sustainable development goals. The effectiveness of such international cooperation**
23 **arrangements, however, depends on the way they are developed and implemented (*high***
24 ***confidence*).** The effectiveness and sustainable development benefits of technology sharing
25 under market conditions appears to be determined primarily by the complexity of technologies,
26 local capabilities and the policy regime. This suggests that the development of planning and
27 innovation capabilities remains necessary, especially in least-developed countries and SIDS.
28 International diffusion of low-emission technologies is also facilitated by knowledge spillovers
29 from regions engaged in clean R&D (*medium confidence*).

30 **The evidence on the role of intellectual property rights (IPR) in innovation is mixed. Some**
31 **literature suggests that it is a barrier while and other sources suggests that it is an enabler**
32 **to the diffusion of climate-related technologies (*medium confidence*).** There is agreement
33 that countries with well-developed institutional capacity may benefit from a strengthened IPR
34 regime, but that countries with limited capabilities might face greater barriers to innovation as
35 a consequence. This enhances the continued need for capacity building. Ideas to improve the
36 alignment of the global IPR regime and addressing climate change include specific
37 arrangements for least-developed countries, case-by-case decision-making and patent-pooling
38 institutions. {16.2.3.3, 16.5, Box 16.10}

39 **Although some initiatives have mobilised investments in developing countries, gaps in**
40 **innovation cooperation remain, including in the Paris Agreement instruments. These**
41 **gaps could be filled by enhancing financial support for international technology**
42 **cooperation, by strengthening cooperative approaches, and by helping build suitable**
43 **capacity in developing countries across all technological innovation system functions**
44 **(*high confidence*).** The implementation of current arrangements of international cooperation

1 for technology development and transfer, as well as capacity building, are insufficient to meet
2 climate objectives and contribute to sustainable development. For example, despite building a
3 large market for mitigation technologies in developing countries, the lack of a systemic
4 perspective in the implementation of the Clean Development Mechanism, operational since the
5 mid-2000s, has only led to some technology transfer, especially to larger developing countries,
6 but limited capacity building and minimal technology development (*medium confidence*). In
7 the current climate regime, a more systemic approach to innovation cooperation could be
8 introduced by linking technology institutions, such as the Technology Mechanism, and
9 financial actors, such as the financial mechanism. {16.5.3}

10 **Countries are exposed to sustainable development challenges in parallel with the**
11 **challenges that relate to climate change. Addressing both sets of challenges**
12 **simultaneously presents multiple and recurrent obstacles that systemic approaches to**
13 **technological change could help resolve, provided they are well managed (*high***
14 ***confidence*).** Obstacles include both entrenched power relations dominated by vested interests
15 that control and benefit from existing technologies, and governance structures that continue to
16 reproduce unsustainable patterns of production and consumption (*medium confidence*). Studies
17 also highlight the potential of cultural factors to strongly influence the pace and direction of
18 technological change. Sustainable solutions require adoption and mainstreaming of locally
19 novel technologies that can meet local needs, and simultaneously address the Sustainable
20 Development Goals (SDGs). Acknowledging the systemic nature of technological innovation,
21 which involve many levels of actors, stages of innovation and scales, can lead to new
22 opportunities to shift development pathways towards sustainability. {16.4, 16.5, 16.6}

23 **An area where sustainable development, climate change mitigation and technological**
24 **change interact is digitalisation. Digital technologies can promote large increases in**
25 **energy efficiency through coordination and an economic shift to services, but they can**
26 **also greatly increase energy demand because of the energy used in digital devices. System-**
27 **level rebound effects may also occur. (*high confidence*)** Digital devices, including servers,
28 increase pressure on the environment due to the demand for rare metals and end-of-life
29 disposal. The absence of adequate governance in many countries can lead to harsh working
30 conditions and unregulated disposal of electronic waste. Digitalization also affects firms'
31 competitiveness, the demand for skills, and the distribution of, and access to, resources. The
32 existing digital divide, especially in developing countries, and the lack of appropriate
33 governance of the digital revolution can hamper the role that digitalization could play in
34 supporting the achievement of stringent mitigation targets. At present, the understanding of
35 both the direct and indirect impacts of digitalization on energy use, carbon emissions and
36 potential mitigation, is limited (*medium confidence*). {Cross-Chapter Box 11 in this chapter,
37 16.2}

38 **Strategies for climate change mitigation can be most effective in accelerating**
39 **transformative change when actions taken to strengthen one set of enabling conditions**
40 **also reinforce and strengthen the effectiveness of other enabling conditions (*medium***
41 ***confidence*).** Applying transition or system dynamics to decisions can help policymakers take
42 advantage of such high-leverage intervention points, address the specific characteristics of
43 technological stages, and respond to societal dynamics. Inspiration can be drawn from the
44 global unit cost reductions of solar PV, which were accelerated by a combination of factors

1 interacting in a mutually reinforcing way across a limited group of countries (*high confidence*).
2 {Box 16.2, Cross-Chapter Box 10 in chapter 14}

3 **Better and more comprehensive data on innovation indicators can provide timely insights**
4 **for policymakers and policy design locally, nationally and internationally, especially for**
5 **developing countries, where such insights are missing more often.** Data needed include on
6 those that can show the strength of technological, sectoral and national innovation systems. It
7 is also necessary to validate current results and generate insights from theoretical frameworks
8 and empirical studies for developing countries contexts. Innovation studies on adaptation and
9 mitigation other than energy and ex-post assessments of the effectiveness of various
10 innovation-related policies and interventions, including R&D, would also provide benefits.
11 Furthermore, methodological developments to improve the ability of Integrated Assessment
12 Models (IAMs) to capture energy innovation system dynamics, and the relevant institutions and
13 policies (including design and implementation), would allow for more realistic assessment.
14 {16.2, 16.3, 16.7}

1 16.1 Introduction

2 Technological change and innovation are considered key drivers of economic growth and social
3 progress (Brandão Santana et al. 2015; Heeks and Stanforth 2015). The economic benefit derived from
4 increased production and consumption of goods as well as services create higher demands for improved
5 technologies (Gossart 2015). Since the Industrial Revolution, however, and notwithstanding the
6 benefits, this production and consumption trend and the technological changes associated to it have also
7 come at the cost of long-term damage to the life support systems of our planet (Alarcón and Vos 2015;
8 Steffen et al. 2015). The significance of the such impacts depends on the technology, but also on the
9 intrinsic characteristics of the country or region analysed (Brandão Santana et al. 2015).

10 Other chapters in this volume have discussed technological change in various ways, including as a
11 framing issue (chapter 1), in the context of specific sectors (chapters 6-11), for specific purposes
12 (chapter 12) and as a matter of policy, international cooperation and finance (chapters 13-15). Chapter
13 2 discusses past trends in technological change and chapters 3 and 4 discuss it in the context of future
14 modelling. In general, implicitly or explicitly, technological change is assigned an important role in
15 climate change mitigation and achieving sustainable development (Thacker et al. 2019), also in past
16 IPCC reports (IPCC 2014, 2018a). Chapter 16 describes how a well-established innovation system at a
17 national level, guided by well-designed policies, can contribute to achieve mitigation and adaptation
18 targets along with broader sustainable development goals avoiding, in the process, undesired
19 consequences of technological changes.

20 The environmental impacts of social and economic activities, including emissions of GHG, are greatly
21 influenced by the rate and direction of technological changes (Jaffe et al. 2000). Technological changes
22 usually designed and used to increase productivity and reduce the use of natural resources can lead to
23 increasing production and consumption of goods and services through different rebound effects that
24 diminish the potential benefits of reducing the pressure on the environment (Grübler 1998; Kemp and
25 Soete 1990; Gossart 2015; Sorrell 2007; Barker et al. 2009).

26 Those environmental impacts depend not only on which technologies are used, but also on how they
27 are used (Grübler et al. 1999a). Technological change is not exogenous to social and economic systems;
28 technologies are not conceived, selected, and applied autonomously (Grubler et al. 2018). Underlying
29 driving forces of the problem, such as more resource intensive lifestyles and larger populations
30 (Hertwich and Peters 2009; UNEP 2014), remain largely unchallenged. Comprehensive knowledge of
31 the direct and indirect effects of technological changes on physical and social systems could improve
32 decision-making, also in those cases where technological change mitigates environmental impacts.

33 A sustainable global future for people and nature requires rapid and transformative societal change by
34 integrating technical, governance (including participation), financial and societal aspects of the
35 solutions to be implemented (Pörtner et al. 2021; Sachs et al. 2019). A growing body of interdisciplinary
36 research from around the world can inform implementation of adaptive solutions that address the
37 benefits and drawbacks of linkages in social-ecological complexity, including externalities and rebound
38 effects from innovation and technological transformation (Pörtner et al. 2021; Balvanera et al. 2017).

39 Technological change and transitional knowledge can reinforce each other. The value of traditional
40 wisdom and its technological practices provide examples of sustainable and adaptive systems that could
41 potentially adapt to and mitigate climate change (Singh et al. 2020; Kuoljok 2019). Peasants and
42 traditional farmers have been able to respond well to climate changes through their wisdom and
43 traditional practices (Nicholls and Alteri 2013). The integration of the traditional wisdom with new
44 technologies can offer new and effective solutions (Galloway McLean 2010).

1 Achieving climate change mitigation and other sustainable development goals thus also requires rapid
 2 diffusion of knowledge and technological innovations. However, these are hampered by various
 3 barriers, some of which are illustrated in Table 16.1 (Markard et al. 2020).

4
 5 **Table 16.1 Overview of Challenges to Accelerated Diffusion of Technological Innovations.** Based on
 6 (Markard et al. 2020)

Challenges	Description	Examples
Innovations in whole systems	Since entire systems are changing, also changes in system architecture are needed, which may not keep pace.	Decentralization of electricity supply and integration of variable sources.
Interaction between multiple systems and subsystems	Simultaneous, accelerating changes multiple systems or sectors, vying for the same resources and showing other interactions.	Electrification of transport, heating and industry all using the same renewable electricity source.
Industry decline and incumbent resistance	Decline of existing industries and businesses can lead to incumbents slowing down change, and resistance from e.g. unions or workers.	Traditional car industry leading to factory closures, demise of coal mining and coal-fired power generation leading to local job loss.
Consumers and social practices	Consumers need to change practices and demand patterns.	Less car ownership in a sharing economy, trip planning for public and non-motorised transport, fuelling practices in electric driving.
Coordination in governance and policy	Increasing complexity of governance requires coordination between multiple levels of government and a multitude of actors relevant to the transition, e.g. communities, financial institutions, private sector.	Multi-level governance between European Commission and member states in Energy Union package.

7 The literature on how, in a systemic way, the barriers to sustainability transition can be overcome in
 8 various circumstances has been growing rapidly over the past decades. A central element is that national
 9 systems of innovation can help achieving both climate change and sustainable development goals, by
 10 integrating new ideas, devices, resources, new and traditional knowledge and technological changes for
 11 more effective and adaptive solutions (Lundvall 1992). At the organizational level, innovation is seen
 12 as a process that can bring value by means of creating more effective products, services, processes,
 13 technologies, policies and business models that are applicable to commercial, business, financial and
 14 even societal or political organizations (Brooks 1980; Arthur 2009).

15 The literature refers to the terms “technology push,” “market pull,” “regulatory push-pull,” and “firm
 16 specific factors” as drivers for innovation, mostly to inform policymakers (Zubeltzu-Jaka et al. 2018).
 17 There has also been growing interest in social drivers, motivated by the recognition of social issues,
 18 such as unemployment and public health, linked to the deployment of innovative low-carbon
 19 technologies (Altantsetseg et al. 2020). Policy and social factors and the diverse trajectories of
 20 innovation are influenced by regional and national conditions (Tariq et al. 2017), and such local needs
 21 and purposes need to be considered in crafting international policies aimed at fostering the global
 22 transition towards increased sustainability (Caravella and Crespi 2020). From this standpoint, a
 23 multidimensional, multi-actor systemic innovation approach would be needed to enhance global
 24 innovation diffusion (de Jesus and Mendonça 2018), especially if this is to lead to overall sustainability
 25 improvements rather than resulting in new sustainability challenges.

1 Policies to mitigate climate change do not always take into account the effects of mitigation
2 technologies on other environmental and social challenges (Arvesen et al. 2011). Policies also often
3 disregard the strong linkages between technological innovation and social innovation; the latter
4 understood as the use of soft technologies that brings about transformation through establishing new
5 institutions, new practices, and new models to create a positive societal impact characterized by
6 collaboration that crosses traditional roles and boundaries, between citizens, civil society, the state, and
7 the private sector (Reynolds et al. 2017). Market forces do not provide sufficient incentives for
8 investment in development or diffusion of technologies, leaving a role for public policy to create the
9 conditions to assure a systemic innovation approach (Popp 2010; Popp and Newell 2012). Moreover,
10 public action is more than just addressing market failure, it is an unalienable element of an innovation
11 system (Mazzucato 2013).

12 Coupling technological innovation with sustainable development and the SDGs would need to address
13 overall social, environmental, and economic consequences, given that public policy is intertwined with
14 innovation, technological changes and other factors in a complex manner. Chapter 16 is organized in
15 the following manner to provide an overview of innovation and technology development and transfer
16 for climate change and sustainable development.

17 Section 16.2 discusses drivers of innovation process, including macro factors that can redirect
18 technological change towards low-carbon options. Representations of these drivers in mathematical and
19 statistical models allow for explaining the past and constructing projections of future technological
20 change. They also integrate the analysis of drivers and consequences of technological change within
21 economic-energy-economy (or integrated assessment) models (see Chapter 3). The section also
22 describes the different phases of innovation and metrics, such as the widely used but also criticized
23 technology readiness levels (TRLs).

24 Section 16.3 discusses innovation as a systemic process based on recent literature. While the innovation
25 process is often stylized as a linear process, innovation is now predominantly seen as a systemic process
26 in that it is a result of actions by, and interactions among, a large set of actors, whose activities are
27 shaped by, and shape, the context in which they operate and the user group with which they are
28 engaging.

29 Section 16.4 presents innovation and technology policy, including technology push (e.g., publicly
30 funded R&D) and demand-pull (e.g., governmental procurement programmes) instruments that
31 addresses potential market failures related to innovation and technology diffusion. The section also
32 assesses the cost-effectiveness and other policy assessment criteria introduced in Chapter 13 of
33 innovation policies.

34 In section 16.5, the chapter assesses the role of international cooperation in technology development
35 and transfer, in particular the mechanisms established under the UNFCCC, but also other international
36 initiatives for technology cooperation. The discussion on international cooperation includes information
37 exchange, research, development and demonstration cooperation, access to financial instruments,
38 intellectual property rights, as well as promotion of domestic capacities and capacity building.

39 Section 16.6 describes the role of technology in sustainable development, including unintended effects
40 of technological changes, and synthesizes the chapter. Finally, section 16.7 discusses gaps in knowledge
41 emerging from this chapter.

42

43

1 **16.2 Elements, drivers and modelling of technology innovation**

2 Models of the innovation process, its drivers and incentives provide a tool for technology assessment,
3 constructing projections of technological change and identifying which macro conditions facilitate
4 development of low-carbon technologies. The distinction between stages of innovation process allows
5 to assess technology readiness (Section 16.2.1). Qualitative and quantitative analysis of main elements
6 underpinning innovation - R&D, learning-by-doing, spillovers allow for explanation of past and project
7 future technological change (Section 16.2.2). In addition, general purpose technologies can play a role
8 in climate change mitigation.

9 In the context of mitigation pathways, the feasibility of any emission reduction targets depends on the
10 ability to promote innovation in low- and zero-carbon technologies, as opposed to any other technology.
11 For this reason, the section reviews the literature of the levers influencing the *direction* of technological
12 change in favour of low- and zero-carbon technologies (Section 16.2.3). Moreover, representation of
13 drivers in mathematical and statistical models from section 16.2.2 allows integrating its analysis with
14 economic and climate effects within IAMs, hence permitting more precise modelling of decarbonisation
15 pathways (Section 16.2.4).

16 In addition to technological innovation, other innovation approaches are relevant in the context of
17 climate mitigation and more broadly sustainable development (Section 16.6). Frugal innovations, i.e.
18 “good enough” innovations that fulfil the needs of non-affluent consumers mostly in developing
19 countries (Hossain 2018), are characterized by low costs, concentration on core functionalities, and
20 optimised performance level (Weyrauch and Herstatt 2016) and are hence often associated with
21 (ecological and social) sustainability (Albert 2019). Grassroots innovations are products, services and
22 processes developed to address specific local challenges and opportunities, and which can generate
23 novel, bottom-up solutions responding to local situations, interests and values. (Dana et al. 2021;
24 Pellicer-Sifres et al. 2018).

25

26 **16.2.1 Stages of the innovation process**

27 The innovation cycle is commonly thought of as having three distinct innovation phases on the path
28 between basic research and commercial application: Research and Development (R&D), demonstration,
29 and deployment and diffusion (IPCC 2007). Each of these phases differs with respect to the kind of
30 activity carried out, the type of actors involved and their role, financing needs and the associated risks
31 and uncertainties. All phases involve a process of trial and error, and failure is common; the share of
32 innovation that successfully reaches the deployment phase is small. The path occurring between basic
33 research to commercialization is not linear (see also Section 16.3); it often requires a long time and is
34 characterized by significant bottlenecks and roadblocks. Furthermore, technologies may regress
35 backwards in the innovation cycle, rather than move forward (Skea et al. 2019). Successfully passing
36 from each stage to the next one in the innovation cycle requires overcoming “valleys of deaths”
37 (Auerswald and Branscomb 2003; UNFCCC 2017), most notably the demonstration phase (Frank et al.
38 1996; Weyant 2011; Nemet et al. 2018). Over time, new and improved technologies are discovered;
39 this often makes the dominant technology obsolete, but this is not discussed here further.

40 Table 16.2 summarizes the different innovation stages and main funding actors, and maps phases into
41 the technology readiness levels (TRLs) discussed in Section 16.2.1.4.

42

1 **Table 16.2 Stages of the innovation process (16.2.1) mapped onto Technology Readiness Levels (16.2.1.4)**

Stage	Main funding actors	Phases	Related TRL
Research and development	Governments	Basic research	1 – Initial idea (basic principles defined)
	Firms	Applied research and technology development	2 – Application formulated (technology concept and application of solution formulated)
			3 – Concept needs validation (solutions need to be prototyped and applied)
			4 – Early prototype (prototype proven in test conditions)
			5 – Full prototype at scale (components proven in conditions to be deployed)
Demonstration	Governments Firms Venture Capital Angel investors	Experimental pilot project or full scale testing	6 – Full prototype at scale (prototype proven at scale in conditions to be deployed)
			7 – Pre-commercial demonstration (solutions working in expected conditions)
			8 – First-of-a-kind commercial (commercial demonstration, full scale deployment in final form)
			9 – Commercial operation in early environment (solution is commercial available, needs evolutionary improvement to stay competitive)
Deployment and diffusion	Firms Private equity Commercial banks Mutual funds	Commercialization and scale up (<i>business</i>)	10 – Integration needed at scale (solution is commercial and competitive but needs further integration efforts) 11 – Proof of stability reached (Predictable growth)
	International organizations and financial institutions NGOs	Transfer

3 **16.2.1.1 Research and Development**

4 This phase of the innovation process focuses on generating knowledge or solving particular problems
5 by creating a combination of artefacts that is intended to perform a particular function, or to achieve a
6 specific goal. R&D activities comprise basic research, applied research and technology development.
7 Basic research is experimental or theoretical work undertaken primarily to acquire new knowledge of
8 the underlying foundations of phenomena and observable facts, without any particular application or
9 use in view. Applied research is original investigation undertaken in order to acquire new knowledge,
10 primarily directed towards a specific, practical aim or objective (OECD 2015a). Importantly, R&D
11 activities can be incremental, i.e. focused on addressing a specific need by marginally improving an
12 already existing technology, or radical, representing a paradigm shift, promoted by new opportunities
13 arising with the accumulation of new knowledge (Mendonça et al. 2018). Technology development,
14 often leading to prototyping, consists of generating a working model of the technology that is usable in
15 the real world, proving the usability and customer desirability of the technology and giving an idea of
16 its design, features and functioning (OECD 2015a). These early stages of technological innovation are
17

1 referred to as “formative phase”, during which the conditions are shaped for a technology to emerge
2 and become established in the market (Wilson and Grubler 2013) and the constitutive elements of the
3 innovation system emerging around a particular technology are set up (see Section 16.3)(Bento et al.
4 2018; Bento and Wilson 2016).

5 The outcomes of R&D are uncertain: the amount of knowledge that will result from any given research
6 project or investment is unknown *ex ante* (Rosenberg 1998). This risk to funders (Goldstein and
7 Kearney 2020) translates into underinvestment in R&D due to low appropriability (Sagar and Majumdar
8 2014; Weyant 2011). In the case of climate mitigation technologies, low innovation incentives for the
9 private sector also result from a negative environmental externality (Jaffe et al. 2005). Furthermore, in
10 absence of stringent climate policies and targets, incumbent fossil-based energy technologies are
11 characterized by lower financing risk, are heavily subsidized (Kotchen 2021; Davis 2014) and
12 depreciate slowly (see Section 16.2.3) (Nanda et al. 2016; Semieniuk et al. 2021; Arrow 1962a). In this
13 context public research funding therefore plays a key role in supporting high-risk R&D both in
14 developed and developing economies: it can provide patient and steady funding not tied to short-term
15 investment returns (see Section 16.4) (Anadon et al. 2014; Mazzucato 2015a; Howell 2017; Zhang et
16 al. 2019; Anadón et al. 2017; Chan and Diaz Anadon 2016; Kammen and Nemet 2007). Public policies
17 also play a role increasing private incentives in energy research and development funding (Nemet 2013).
18 R&D statistics are an important indicator of innovation and are collected following the rules of the
19 Frascati Manual (OECD 2015b) (Section 16.3.3, Box 16.3, Table 16.7).

20 **16.2.1.2 Demonstration**

21 Demonstration is carried out through pilot projects or large-scale testing in the real world. Successfully
22 demonstrating a technology shows its utility and that it is able to achieve its intended purpose and,
23 consequently, that the risk of failure is reduced (i.e. that it has market potential) (Hellsmark et al. 2016).
24 Demonstration projects are an important step to promote the deployment of low-carbon energy and
25 industrial technologies in the context of the transition. government funding often plays a large role in
26 energy technology demonstration projects because scaling up hardware energy technologies is
27 expensive and risky (Brown and Hendry 2009; Hellsmark et al. 2016). Governments’ engagement in
28 low-carbon technology demonstration also signals support for business willing to take the investment
29 risk (Mazzucato 2016). Venture capital, traditionally not tailored for energy investment, can play an
30 increasingly important role also thanks to the incentives (e.g. through de-risking) provided by public
31 funding and policies (Gaddy et al. 2017; IEA 2017a).

32 **16.2.1.3 Deployment and diffusion**

33 Deployment entails producing a technology at large scale and scaling up its adoption use across
34 individual firms or households in a given market, and across different markets (Jaffe 2015). In the
35 context of climate change mitigation and adaptation technologies, the purposeful diffusion to
36 developing countries, is referred to as “technology transfer”. Most recently, the term “innovation
37 cooperation” has been proposed to indicate that technologies need to be co-developed and adapted to
38 local contexts (Pandey et al. 2021). Innovation cooperation is an important component of stringent
39 mitigation strategies as well as international agreements (see Section 16.5).

40 Diffusion is often sluggish due to lock-in of dominant technologies (Liebowitz and Margolis 1995;
41 Unruh 2000; Ivanova et al. 2018), as well as the time needed to diffuse information about the
42 technologies, heterogeneity among adopters, the incentive to wait until costs fall even further, the
43 presence of behavioural and institutional barriers and the uncertainty surrounding mitigation policies
44 and long-term commitments to climate targets (Corey 2014; Haelg et al. 2018; Gillingham and Sweeney
45 2012; Jaffe 2015). In addition, novel technology has been hindered by the actions of powerful
46 incumbents who accrue economic and political advantages over time, as in the case of renewable
47 energy generation (Unruh 2002; Supran and Oreskes 2017; Hoppmann et al. 2019).

1 Technologies have been shown to penetrate the market with a gradual non-linear process in a
2 characteristic logistic (S-shaped) curve (Rogers 2003; Grübler 1996). The time needed to reach
3 widespread adoption varies greatly across technologies relevant for adaptation and mitigation (Gross et
4 al. 2018); in the case of energy technologies, the time needed for technologies to get from a 10 to 90%
5 market share of saturation ranges between 5 to over 70 (Wilson 2012). Investment in commercialization
6 of low-emission technology is largely provided by private financiers; however, governments play a key
7 role in ensuring incentives through supportive policies, including R&D expenditures providing signals
8 to private investors (Haelg et al. 2018), pricing carbon dioxide emissions, public procurement,
9 technology standards, information diffusion and the regulation for end-life cycle treatment of products
10 (Cross and Murray 2018) (see Section 16.4).

11 **16.2.1.4 Technology Readiness Levels**

12 Technology Readiness Levels (TRLs) are a categorization that enables consistent, uniform discussions
13 of technical maturity across different types of technology. They were developed by NASA in the 1970s
14 (Mankins 2009, 1995) and originally used to describe the readiness of components forming part of a
15 technological system. Over time, more classifications of TRLs have been introduced, notably the one
16 used by the EU. Most recently, the IEA extended previous classifications to include the later stages of
17 the innovation process (IEA 2020b) and applied it to compare the market readiness of clean energy
18 technologies and their components (OECD 2015a; IEA 2020b). TRLs are currently widely used by
19 engineers, business people, research funders and investors, often to assess the readiness of whole
20 technologies rather than single components. To determine a TRL for a given technology, a Technology
21 Readiness Assessment (TRA) is carried out to examine programme concepts, technology requirements,
22 and demonstrated technology capabilities. In the most recent version of the IEA (IEA 2020b), TRLs
23 range from 1 to 11, with 11 indicating the most mature (see Table 16.2).

24 The purpose of TRLs is to support decision making. They are applied to avoid the premature application
25 of technologies, which would lead to increased costs and project schedule extension (US Department
26 of Energy 2011). They are used for risk management, and can also be used to make decisions regarding
27 technology funding and to support the management of the R&D process within a given organization or
28 country (De Rose et al. 2017).

29 In practice, the usefulness of TRLs is limited by several factors. These include limited applicability in
30 complex technologies or systems, the fact that they do not define obsolescence, nor account for
31 manufacturability, commercialization or the readiness of organizations to implement innovations
32 (European Association of Research Technology Organisations 2014) and do not consider any type of
33 technology-system mismatch or the relevance of the products' operation environment to the system
34 under consideration (Mankins 2009). Many of these limitations can be eased by using TRLs in
35 combination with other indicators such as System Readiness Levels and other economic indicators on,
36 for example, investments and returns (IEA 2020b).

37

38 **16.2.2 Sources of technological change**

39 The speed of technological change could be explained with the key drivers of innovations process: R&D
40 effort, learning-by-doing and spillover effects. In addition, new innovations are sometimes enabled by
41 the development of general purpose technologies, such as digitalization.

42 **16.2.2.1 Learning-by-doing and research and development**

43 Learning by doing and R&D effort are two factors commonly used by the literature to explain past and
44 project future speed of technological change (Klaassen et al. 2005; Mayer et al. 2012; Bettencourt et al.
45 2013). Learning-by-doing is the interaction of workers with new machines or processes that allows
46 them to use them more efficiently (Arrow 1962b). R&D effort is dedicated to looking for new solutions

1 (e.g. blueprints) that could increase the efficiency of existing production methods or result in entirely
2 new methods, products or services (see section 16.2.1.1).

3 Learning-by-doing and research and development are interdependent. Young (1993) postulates that
4 learning-by-doing cannot continue forever without R&D because it is bounded by an upper physical
5 productivity limit of an existing technology. Research and development can shift this limit because it
6 allows replacing the existing technology with a new one. On other hand, incentives to invest in R&D
7 depend on future cost of manufacturing, which in turn depend on the scale of learning-by-doing. The
8 empirical evidence for virtuous circle between costs reduction, market growth and R&D were found in
9 the case of PV market ((Watanabe et al. 2000); see also Box 16.4), but could also lead to path
10 dependency and lock-in (Erickson et al. 2015). Section 16.4.4 and Chapter 13 Section 13.7.3.1. discuss
11 how simultaneous use of technology push and pull policies could amplify effects of research and
12 learning.

13 The benefits of R&D and learning-by-doing are larger at the economy level than at the firms level
14 (Romer 1990; Arrow 1962b). As a result, the market, left to its own, tends to generate less investment
15 than socially optimal. For instance, if the cost of a technology is too high before a large amount of
16 learning-by-doing has occurred, there is a risk that it will not be adopted by the market even if it is
17 economically advantageous for the society. Indeed, initially new technologies are often expensive and
18 cannot compete with the incumbent technologies (Cowan 1990). Large numbers of adopters could lower
19 this cost via learning-by-doing to a level sufficient to beat the incumbent technology (Gruebler et al.
20 2012). However, firms could hesitate to be the first adopter and bear the high cost (Isoard and Soria
21 2001). If this disadvantage overwhelms the advantages of being a first mover¹ and if adopters are not
22 able to coordinate, it will lead to situation of a lock-in (Gruebler et al. 2012).

23 The failure of markets to deliver the size of R&D investment and learning-by-doing that would be
24 socially optimal is one of the justifications of government intervention. Policies to address these market
25 failures can be categorized as technology push and demand pull policies. The role of these policies is
26 explained in Table 16.3. Section 16.4 discusses individual policy instruments in greater detail.

27

28 **Table 16.3 Categories of policies and interventions accelerating technological changes, the factors**
29 **promoting them and slowing them down, illustrated with examples**

	What it refers to:	What promotes technological change	What slows down technological change	Examples
Technology Push	Support the creation of new knowledge to make it easier to invest in innovation	R&D, funding and performance of early demonstrations (Brown and Hendry 2009; Hellsmark et al. 2016)	Inadequate supply of trained scientists and engineers (Popp and Newell 2012); gap with demand pull (Grübler et al. 1999b).	Japan's Project Sunshine, the US Project Independence in the 1970s. Breakthrough Energy Coalition and Mission Innovation, respectively private- and public-sector international collaborations to respectively focus energy innovation and double energy R&D, both initiated concurrently with the Paris Agreement in 2015 (Sanchez and Sivaram 2017).

FOOTNOTE¹ see e.g. (Spence 1981) and (Bhattacharya 1984) for discussion of first-mover advantages

Demand Pull	Instruments creating market opportunities.	Enlarging potential markets, increasing adoption of new fuels and mitigation technology. Digital innovations Social innovation and awareness	Willingness of consumers to accept new technology. Policy and political volatility can deter investment.	Subsidies for wind power California, the German feed-in tariff for PV, quotas for electric vehicles in China (Wang et al. 2017a) and Norway (Pereirinha et al. 2018) Biofuels (Brazil); Social innovation with Wind Energy (Denmark, Germany)
-------------	--	--	--	--

1 The size of learning-by-doing effect is quantified in literature using learning rates i.e. estimates of
2 negative correlation between costs and size of deployment of technologies. The results from this
3 literature include estimates for energy technologies (McDonald and Schrattenholzer 2001), electricity
4 generation technologies (Rubin et al. 2015; Samadi 2018), for storage (Schmidt 2017), for end-of-pipe
5 control (Kang et al. 2020) and for energy demand and energy supply technologies (Weiss et al. 2010).
6 Meta-analyses find learning rates vary across technologies, within technologies and over time (Wei et
7 al. 2017; Nemet 2009a; Rubin et al. 2015). Moreover, different components of one technology have
8 different learning rates (Elshurafa et al. 2018). Central tendencies are around 20% cost reduction for
9 each doubling of deployment (McDonald and Schrattenholzer 2001).

10 Studies of correlation between cumulative deployment of technologies and costs are not sufficiently
11 precise to disentangle the causal effect of increase in deployment from the causal effects of research
12 and development and other factors (Nemet 2006). Numerous subsequent studies attempted to, amongst
13 others, separate the effect of learning-by-doing and research and development (Klaassen et al. 2005;
14 Mayer et al. 2012; Bettencourt et al. 2013), economies of scale (Arce 2014), and knowledge spillovers
15 (Nemet 2012). Once those other factors are accounted for, some empirical studies find that the role of
16 learning-by-doing in driving down the costs becomes minor (Kavlak et al. 2018; Nemet 2006). In
17 addition the relation could reflect reverse causality: increase in deployment could be an effect (and not
18 a cause) of a drop in price (Witajewski-Baltvilks et al. 2015; Nordhaus 2014). Nevertheless, in some
19 applications, learning curves can be a useful proxy and heuristic (Nagy et al. 2013).

20 The negative relation between costs and experience is a reason to invest in a narrow set of technologies;
21 the uncertainty regarding the parameters of this relation is the reason to invest in wider ranges of
22 technologies (Way et al. 2019; Fleming and Sorenson 2001). Concentrating investment in narrow sets
23 of technologies (specialization) enables fast accumulation of experience for these technologies and large
24 cost reductions. However, when the potency of technology is uncertain, one does not know which
25 technology is truly optimal in the long-run. The narrower the set the higher the risk that the optimal
26 technology will not be supported, and hence will not benefit from learning-by-doing. Widening the set
27 of supported technologies would reduce this risk (Way et al. 2019). Uncertainty is present because noise
28 in historical data hides the true value of learning rates as well as because of unanticipated future shocks
29 to technology costs (Lafond et al. 2018). Ignoring uncertainty in integrated assessment models implies
30 that these model results are biased towards supporting narrow set of technologies neglecting the benefits
31 of decreasing risk through diversification (Sawulski and Witajewski-Baltvilks 2020).

32 **16.2.2.2 Knowledge spillovers**

33 Knowledge spillovers drive continuous technological change (Rivera-Batiz and Romer 1991; Romer
34 1990) and are for that reason relevant to climate technologies as well as incumbent, carbon-intensive
35 technologies. Knowledge embedded in innovations by one innovator give an opportunity for others to
36 create new innovations and increase the knowledge stock even further. The constant growth of
37 knowledge stock through spillovers translates into constant growth of productivity and cost reduction.

1 By allowing for experimenting with existing knowledge and combining different technologies,
2 knowledge spillovers can result in the emergence of novel technological solutions, which has been
3 referred to as recombinant innovation (Weitzman 1998; Olsson and Frey 2002; Tsur and Zemel 2007;
4 Arthur 2009; Fleming and Sorenson 2001). Recombinant innovations speed up technological change
5 by combining different technological solutions, and make things happen that would be impossible with
6 only incremental innovations (Safarzyńska and van den Bergh 2010; van den Bergh 2008; Frenken et
7 al. 2012). It has been shown that 77% of all patents granted between 1790 and 2010 in the US are coded
8 by a combination of at least two technology codes (Youn et al. 2015). Spillovers related to energy and
9 low-carbon technologies has been documented by a number of empirical studies (*high confidence*)
10 (Popp 2002; Aghion et al. 2013; Witajewski-Baltvilks et al. 2017; Verdolini and Galeotti 2011; Conti
11 et al. 2018). The presence of spillovers can have both positive and negative impacts on climate change
12 mitigation (*high confidence*).

13 The spillover effect associated with innovation in carbon-intensive technologies may lead to lock-in of
14 fossil-fuel technologies. Continuous technological change of carbon-intensive industry raises the bar
15 for clean technologies: a larger drop in clean technologies' cost is necessary to become competitive
16 (Acemoglu et al. 2012; Aghion et al. 2013). The implication is that delaying climate policy increases
17 the cost of that policy (Aghion 2019).

18 On the other hand, the spillover effect associated with innovation in low-emission technologies increase
19 the potency of climate policy (Aghion 2019). For instance, a policy that encourages clean innovation
20 leads to accumulation of knowledge in clean industry which, through spillover effect encourages further
21 innovation in clean industries. Once the stock of knowledge is sufficiently large, the value of clean
22 industries will be so high, that technology firms will invest there even without policy incentives. Once
23 this point is reached, the policy intervention can be discontinued (Acemoglu et al. 2012).

24 In addition, the presence of spillovers implies that a unilateral effort to reduce emissions in one region
25 could reduce emissions in other regions (*medium confidence*) (Gerlagh and Kuik 2014; Golombek and
26 Hoel 2004). For instance, in the presence of spillovers, a carbon tax that incentivises clean technological
27 change increases the competitiveness of clean technologies not only locally, but also abroad. The size
28 of this effect depends on the size of spillovers. If they are sufficiently strong, the reduction of emissions
29 abroad due to clean technological change could be larger than the increase of emissions due to carbon
30 leakage (Gerlagh and Kuik 2014). Different types of carbon leakage are discussed in Chapter 13,
31 Section 13.7.1 and other consequences of spillovers for the design of policy are discussed in Chapter
32 13, Section 13.7.3.

33 **16.2.2.3 General purpose technologies and digitalization**

34 General purpose technologies (GPTs) provide solutions that could be applied across sectors and
35 industries (Goldfarb 2011) by creating technological platforms for a growing number of interrelated
36 innovations. Examples of GPTs relevant to climate change mitigation are hydrogen and fuel cell
37 technology, which may find applications in transport, industry and distributed generation (Hanley et al.
38 2018), and nanotechnology which played a significant role in advancement of all the different types of
39 renewable energy options (Hussein 2015). Assessing the environmental, social and economic
40 implications of such technologies, including increased emissions through energy use, is challenging
41 (see Chapter 5, Section 5.3.4.1 and Cross-Chapter Box 11 below).

42 Several GPTs relevant for climate mitigation and adaptation emerged as a result digitalization, namely
43 the adoption or increase in use of information and communication technologies (ICTs) by citizens,
44 organizations, industries or countries and the associated restructuring of several domains of social life
45 and of the economy around digital technologies and infrastructures (IEA 2017b; Brennen and Kreiss
46 2016). The digital revolution is underpinned by innovation in key technologies, e.g. ubiquitous
47 connected consumer devices such as mobile phones (Grubler et al. 2018), rapid expansions of global
48 internet infrastructure and access (World Bank 2014), and steep cost reductions and performance

1 improvements in computing devices, sensors, and digital communication technologies (Verma et al.
2 2020). The increasing the pace at which the physical and digital worlds are converging increase the
3 relevance of disruptive digitalization in the context of climate mitigation and sustainability challenges
4 (European Commission 2020) (see Cross-chapter Box 11 in this chapter and Chapter 4, Section 4.4.1).

5 Digital technologies require energy, but increase efficiency, potentially offering technology-specific
6 GHG emission savings; they also have larger system wide impacts (Kaack et al. 2021). In industrial
7 sectors, robotization, smart manufacturing (SM), internet of things (IoT), artificial intelligence (AI),
8 and additive manufacturing (AM or 3D printing), have the potential to reduce material demand and
9 promote energy management (Chapter 11, Section 11.3.4.2). Smart mobility is changing transport
10 demand and efficiency (Chapter 10, Section 10.2.3). Smart devices in buildings, the deployment of
11 smart grids and the provision of renewable energy increase the role of demand-side management
12 (Serrenho and Bertoldi 2019) (Chapter 9, Sections 9.4 and 9.5), and support the shift away from asset
13 redundancy (Chapter 6, Section 6.4.3). Digital solutions are equally important on the supply side, for
14 example by accelerating innovation with simulations and deep learning (Rolnick et al. 2021) or realizing
15 flexible and decentralized opportunities through energy-as-a-service concepts and particularly with
16 Pay-As-You-Go (Chapter 15, Box 15.8, Table 1).

17 Yet, increased digitalization could give increase energy demand, thus wiping away potential efficiency
18 benefits, unless appropriately governed (IPCC 2018a). Moreover, digital technologies could negatively
19 impact labour demand and increase inequality (Cross-Chapter Box 11 in this chapter).

21 **START CCB 11 HERE**

22 **Cross-Chapter Box 11: Digitalization: efficiency potentials and governance considerations**

23 Felix Creutzig (Germany), Elena Verdolini (Italy), Paolo Bertoldi (Italy), Luisa F. Cabeza
24 (Spain), María Josefina Figueroa Meza (Venezuela/Denmark), Kirsten Halsnæs (Denmark), Joni
25 Jupesta (Indonesia), Şiir Kilkış (Turkey), Michael Koenig (Germany), Eric Masanet (the United States
26 of America), Nikola Milojevic-Dupont (France), Joyashree Roy (India/Thailand), Ayyoob Sharifi
27 (Iran/Japan).

28 **Digital technologies impact positively and negatively GHG emissions through their own carbon**
29 **footprint, via technology application for mitigation, and via induced larger social change. Digital**
30 **technologies also raise broader sustainability concerns due to their use of rare materials and**
31 **associated waste, and their potential negative impact on inequalities and labour demand.**

32 **Direct impacts emerge because digital technologies consume large amounts of energy, but also**
33 **have the potential to steeply increase energy efficiency in all end-use sectors through material**
34 **input savings and increased coordination (*medium evidence, medium agreement*)** (Horner et al.
35 2016; Jones 2018) (Huang et al. 2016; IEA 2017b). Global energy demand from digital appliances
36 reached 7.14 EJ in 2018 (Chapter 9, Box 9.5), implying higher related carbon emissions. However, a
37 small smart phone offers services previously requiring many different devices (Grubler et al. 2018).
38 Demand for data services is increasing rapidly; quantitative estimates of the growth of associated energy
39 demand range from slow and marginal to rapid and sizeable, depending the efficiency trends of digital
40 technologies (see Chapter 5.3.4.1)(Avgerinou et al. 2017; Stoll et al. 2019; Vranken 2017; Masanet et
41 al. 2020). Renewable energy serves as low-carbon energy provider for the operation of data centre,
42 which in turn can provide waste heat for other purposes. Digital technologies can markedly increase the
43 energy efficiency of mobility and residential and public buildings, especially in the context of systems
44 integration (IEA 2020a). Reduction in energy demand and associated GHG emissions from buildings
45 and industry while maintaining service levels equal is estimated at 5 to 10%, with larger savings
46 possible. Approaches include building energy management systems (BEMS), home energy

1 management system (HEMS), demand response and smart charging (Cross-Chapter Box 11, Table 1.
 2 Data centres can also play a role in energy system management, e.g., by increasing renewable energy
 3 generation through predictive control (Dabbagh et al. 2019), and by helping drive the market for battery
 4 storage and fuel cells (Riekstin et al. 2014). Temporal and spatial scheduling of electricity demand can
 5 provide about 10 GW in demand response in the European electricity system in 2030 (Koronen et al.
 6 2020; Wahlroos et al. 2017, 2018; Laine et al. 2020).

7 **However, system-wide effects may endanger energy and GHG emission savings (*high evidence,***
 8 ***high agreement*)**. Economic growth resulting from higher energy and labour productivities can increase
 9 energy demand (Lange et al. 2020) and associated GHG emissions. Importantly, digitalization can also
 10 benefit carbon-intensive technologies (Victor 2018). Impacts on GHG emissions are varied in smart
 11 and shared mobility systems, as ride hailing increases GHG emissions due to deadheading, whereas
 12 shared pooled mobility and shared cycling reduce GHG emissions, as occupancy levels and/or weight
 13 per person km transported improve (Chapter 5, Section 5.3). Energy and GHG emissions impacts from
 14 the ubiquitous deployment of smart sensors and service optimization applications in smart cities through
 15 are insufficiently assessed in the literature (Milojevic-Dupont and Creutzig 2021). Systemic effects have
 16 wider boundaries of analysis, including broader environmental impacts (e.g. demand for rare materials,
 17 disposal of digital devices). These need to be integrated holistically within policy design (Kunkel and
 18 Matthes 2020), but they are difficult to quantify and investigate (Bieser and Hilty 2018). Policies and
 19 adequate infrastructures and choice architectures can help manage and contain the negative
 20 repercussions of systemic effects (Section 5.4, 5.6, 9.9).

21
 22 **Cross-chapter Box 11, Table 1. Selected sector approaches for reducing GHG emissions that are**
 23 **supported by new digital technologies. Contributions of digitalization include a) supporting role (+), b)**
 24 **necessary role in mix of tools (++) , c) necessary unique contribution (+++), but digitalization may also**
 25 **increase emissions (-). See also chapters 5, 8, 9, and 11.**

Sector	Approach	Quantitative evidence	Contribution of digitalization	Systems perspective and broader societal impacts	References
Residential energy use	Nudges (feedback, information, etc.)	2-4% reduction in global household energy use possible	+ in combination with monetary incentives, non-digital information	New appliances increase consumption	(Buckley 2020; Zangheri et al. 2019; Khanna et al. 2021; Nawaz et al. 2020)
Smart mobility	Shared mobility and digital feedback (ecodriving)	Reduction for shared cycling and shared pooled mobility; increase for ride hailing/ride sourcing; reduction for eco-driving	- or ++ Apps together with big data and machine learning algorithm key precondition for new shared mobility	Ride hailing increases GHG emissions, especially due to deadheading	(OECD and ITF 2020; Zeng et al. 2017)
Smart cities	Using digital devices and big data to make urban transport and building	Precise data about roadway use can reduce material intensity and associated GHG	++ Big data analysis necessary for optimization	Efficiency gains are often compensated by more driving and other rebound effects; privacy	(Milojevic-Dupont and Creutzig 2021) (Chapter 10, Box 10.1)

	use more efficient	emissions by 90%,		concerns linked with digital devices in homes	
Agriculture	Precision agriculture through sensors and satellites providing information on soil moisture, temperature, crop growth and livestock feed levels,	Very high potential for variable-rate nitrogen application, moderate potential for variable-rate irrigation	+ ICTs provide information and technologies which enables farmers to increase yields, optimize crop management, reduce fertilizers and pesticides, feed and water; increases efficiency of labour-intensive tasks	The digital divide is growing fast, especially between modern and subsistence farming; Privacy and data may erode trust in technologies	(Townsend et al. 2019; Deichmann et al. 2016; Soto Embodas et al. 2019; Chlingaryan et al. 2018)
Industry	Industrial Internet of Things (IIoT)	Process, activity & functional optimization increases energy and carbon efficiency	++ increased efficiency ++ 1.3 Gt CO ₂ -eq estimated abatement potential in manufacturing + promote sustainable business models	Optimization in value chains can reduce wasted resources	(GeSI 2012; Parida et al. 2019; Rolnick et al. 2021; Wang et al. 2016)
Load management and battery storage optimization	Big data analysis for optimizing demand management and using flexible load of appliances with batteries	Reduces capacity intended for peak demand, shifts demand to align with intermittent renewable energy availability	+ Accelerated experimentation in material science with artificial intelligence ++ / +++ Forecast and control algorithms for storage and dispatch management	Facilitate integration of renewable energy sources Improve utilization of generation assets System-wide rebound effects possible	(Akorede et al. 2010; Hirsch et al. 2018; de Sisternes et al. 2016; Sivaram 2018a; Gür 2018; Aghaei and Alizadeh 2013; Vázquez-Canteli and Nagy 2019; Voyant et al. 2017) (Chapter 6, Section 6.4)

1

2 **Broader societal impacts of digitalization can also influence climate mitigation because of induced**
3 **demand for consumption goods, impacts on firms' competitiveness, changes the demand for skills**
4 **and labour, worsening of inequality – including reduced access to services due to the digital divide**
5 **– and governance aspects (*low evidence, medium agreement*)** (Chapter 4, Section 4.4, Chapter 5,
6 Sections 5.3, 5.6). Digital technologies expand production possibilities in sectors other than ICTs
7 through robotics, smart manufacturing, and 3D printing, and have major implications on consumption
8 patterns (Matthess and Kunkel 2020). Initial evidence suggests that robots displace routine jobs and
9 certain skills, change the demand for high-skilled and low-skilled workers, and suppress wages
10 (Acemoglu and Restrepo 2019). Digitalization can thus reduce consumers' liquidity and consumption
11 (Mian et al. 2020) and contribute to global inequality, including across the gender dimension, raising
12 fairness concerns (Kerras et al. 2020; Vassilakopoulou and Hustad 2021). Digital technologies can lead
13 to additional concentration in economic power (e.g. Rikap 2020) and lower competition; open source

1 digital technologies can however counter this tendency (e.g. Rotz et al. 2019). Digital technologies play
2 a role in mobilizing citizens for climate and sustainability actions (Westerhoff et al. 2018; Segerberg
3 2017).

4 **Whether the digital revolution will be an enabler or a barrier for decarbonization will ultimately**
5 **depend on the governance of both digital decarbonization pathways and digitalization more in**
6 **general (*medium evidence, high agreement*).** The understanding of the disruptive potential of the wide
7 range of digital technologies is limited due to their ground-breaking nature, which makes it hard to
8 extrapolate from previous history/experience. Municipal and national entities can make use of digital
9 technologies to manage and govern energy use and GHG emissions in their jurisdiction (Bibri 2019a,b)
10 and break down solution strategies to specific infrastructures, building, and places, relying on remote
11 sensing and mapping data, and contextual (machine-) learning about their use (Milojevic-Dupont and
12 Creutzig 2021). Mobility apps can provide mobility-as-a-service access to cities ensuring due
13 preference to active and healthy modes (see 9.9 for the example of the Finnish city of Lahti). Trusted
14 data governance can promote the implementation of local climate solutions, supported by available big
15 data on infrastructures and environmental quality (Hansen and Porter 2017; Hughes et al. 2020).
16 Governance decisions, such as taxing data, prohibiting surveillance technologies, or releasing data that
17 enable accountability can change digitalization pathways, and thus underlying GHG emission (Hughes
18 et al. 2020).

19 **Closing the digital gap in developing countries and rural communities enables an opportunity for**
20 **leapfrogging (*medium evidence, medium agreement*).** Communication technologies (such as mobile
21 phones) enable participation of rural communities, especially in developing countries, and promote
22 technological leapfrogging, e.g. decentralized renewable energies and smart farming (Ugur and Mitra
23 2017; Foster and Azmeh 2020; Arfanuzzaman 2021). Digital technologies have sector-specific
24 potentials and barriers, and may benefit certain regions/areas/socioeconomic groups more than others.
25 For example, integrated mobility services benefit cities more than rural and peripheral areas (OECD
26 2017).

27 **Appropriate mechanisms also need to be designed to govern digitalization as megatrend (*medium***
28 ***evidence, high agreement*).** Digitalization is expected to be a fast process, but this transformation takes
29 place against entrenched individual behaviours, existing infrastructure, the legacy of time frames,
30 vested interest and slow institutional processes and requires trust from consumers, producers and
31 institutions. A core question relates to who controls and manages data created by everyday operations
32 (calls, shopping, weather data, service use, etc.). Regulations that limit or ban the expropriation and
33 exploitation of behavioural data, sourced via smart phones, represent crucial aspects in digitalization
34 pathways, alongside the possibility to create climate movements and political pressure from the civil
35 society. Governance mechanisms need to be developed to ensure that digital technologies such as
36 artificial intelligence take over ethical choices (Craglia et al. 2018; Rahwan et al. 2019). Appropriate
37 governance is necessary for digitalization effectively work in tandem with established mitigation
38 technologies and choice architectures. Consideration of system-wide effects and overall management
39 is essential to avoid run-away effects. Overall governance of digitalization remains a challenge, and
40 will have large-scale repercussions on energy demand and GHG emissions.

41 **END CCB 11 HERE**

42 **16.2.2.4 Explaining past and projecting future technology cost changes**

43 Researchers and policymakers alike are interested in using observed empirical patterns of learning to
44 project future reductions in costs of technologies. Studies cutting across a wide range of industrial
45 sectors (not just energy) have tried to relate cost reductions to different functional forms, including cost
46 reductions as a function of time (Moore's law) and cost reductions as a function of production or

1 deployment (Wright's law, also known as Henderson's law), finding that those two forms perform better
2 than alternatives combining different factors, with costs as a function of production (Wright's law)
3 performing marginally better (Nagy et al. 2013). A comparison of expert elicitation and model-based
4 forecasts of the future cost of technologies for the energy transition indicates that model-based forecast
5 medians were closer to the average realized values in 2019 (Meng et al. 2021).

6 Recent studies attempt to separate the influence of learning-by-doing (which is a basis of Wright's law)
7 versus other factors in explaining cost reductions specifically in energy technologies. Some studies
8 explain cost reductions with two factors: cumulative deployment (as proxy for experience) and R&D
9 investment (see the "two factor" learning curve (Klaassen et al. 2005). However, reliable information
10 on public energy R&D investments for developing countries is not systematically collected. Available
11 data for OECD countries cannot be precisely assigned to specific industrial sectors or sub-technologies
12 (Verdolini et al. 2018). Some learning-curve studies take into account that historical variation in
13 technology costs could be explained by variation in key materials and fuel costs (for example steel costs
14 for wind turbines (Qiu and Anadon 2012) silicon costs (Kavlak et al. 2018; Nemet 2006) coal and coal
15 plant construction costs (McNerney et al. 2011). Economies of scale played a significant role in the
16 PV cost reductions since the early 2000s (Yu et al. 2011) (See also Box 16.4), which can also be the
17 case in organic PV technologies (Gambhir et al. 2016; Kavlak et al. 2018).

19 **16.2.3 Directing technological change**

20 Technological change is characterized not only by its speed, but also its direction. The early works that
21 considered the role of technology in economic and productivity growth (Solow 1957; Nelson and Phelps
22 1966) assumed that technology can move forward along only one dimension - every improvement led
23 to an increase in efficiency and increased demand for all factors of production. This view however
24 ignores the potency of technological change to alter the otherwise fixed relation between economic
25 growth and the use of resources.

26 Technological change that saves fossil fuels could decouple economic growth and CO₂ emissions
27 (Acemoglu et al. 2014; Hémous 2016; Grecker et al. 2018; Acemoglu et al. 2012). Saving of fossils
28 could be obtained with increasing efficiency of producing alternatives to fossils (Acemoglu et al. 2012,
29 2014). This is the case of oil consumption by combustion engine cars which could be substituted with
30 electric cars (Aghion et al. 2013). If there is no close substitute to dirty resource, then its intensity in
31 production could still be reduced by increasing efficiency of the dirty resource relative to efficiency of
32 other inputs (Hassler et al. 2012; André and Smulders 2014; Witajewski-Baltvilks et al. 2017). For
33 instance, energy efficiency improvement leads to drop in relative demand for energy (Hassler et al.
34 2012; Witajewski-Baltvilks et al. 2017).

35 **16.2.3.1 Determinants of technological change direction: prices, market size and government**

36 Firms change their choice of technology upon change in prices: when one input (e.g. energy) becomes
37 relatively expensive, firms pick technologies which allow them to economize on that input, according
38 to price-induced technological change theory (Reder and Hicks 1965; Samuelson 1965; Sue Wing
39 2006). For example, an increase in oil price will lead to a choice of fuel-saving technologies. Such
40 response of technological change was evident during the oil-price shocks in the 1970s (Hassler et al.
41 2012). Technological change that is induced by an increase in price of a resource can never lead to an
42 increase in use of that resource. In other words, rebound effects associated induced technological change
43 can never offset the saving effect of that technological change (Antosiewicz and Witajewski-Baltvilks
44 2021).

45 The impact of energy prices on the size of low-carbon technological change is supported by large
46 number of empirical studies (Popp 2019; Grubb and Wieners 2020). Studies document that higher

1 energy prices are associated with higher number of low-carbon energy or energy efficiency patents
2 (Noailly and Smeets 2015; Ley et al. 2016; Lin and Chen 2019; Newell et al. 1999; Popp 2002;
3 Witajewski-Baltvilks et al. 2017; Verdolini and Galeotti 2011). Sue Wing (2008) finds that innovation
4 induced by energy prices had a minor impact on the decline in U.S. energy intensity in the last decades
5 of 20th century and that autonomous technological change played a more important role. Several studies
6 explore the impact of a carbon tax on green innovation (see Section 16.4). However, disentangling the
7 effect of policy tools is complex because presence of some policies could distort the functioning of
8 other policies (Böhringer and Rosendahl 2010; Fischer et al. 2017) and because the impact of policies
9 could be lagged in time (Antosiewicz and Witajewski-Baltvilks 2021).

10 The direction of technological change depends also on the market size for dirty technologies relative to
11 the size of other markets (Acemoglu et al. 2014). Due to this dependence, climate and trade policy
12 choices in a single region can alter the direction of technological change at the global level (see Section
13 16.2.3.3).

14 The value of the market for clean technologies is determined not only by a current but also by firm's
15 expectations of future stream of profits (Alkemade and Suurs 2012; Greaker et al. 2018; Aghion 2019).
16 One implication is that bolstering the credibility and durability of policies related to low-carbon
17 technology is crucial to accelerating technological change and inducing the private sector investment
18 required (Helm et al. 2003), especially in rapidly growing economies of Asia and Africa who are on the
19 brink of making major decisions about the type of infrastructure they build as they grow, develop, and
20 industrialize (Nemet et al. 2017).

21 If governments commit to climate policies, firms expect that the future size of markets for clean
22 technologies will be large and they are eager to redirect research effort towards development of these
23 technologies today. Furthermore the commitment would also incentivise acquiring skills that could
24 further reduce the costs of those technologies (Aghion 2019). However, historical evidence shows that
25 policies related to energy and climate over the long term have tended to change (Nemet et al. 2013;
26 Taylor 2012; Koch et al. 2016). Still, where enhancing policy durability has proven infeasible, multiple
27 uncorrelated potentially overlapping policies can provide sufficient incentives (Nemet 2010).

28 **16.2.3.2 Determinants of direction of technological change: financial markets**

29 The challenges of investing in innovation in energy when compared to other important areas, such as
30 IT and medicine are also reflected in the trends in venture capital funding. Research found that early-
31 stage investments in clean-tech companies were more likely to fail and returned less capital than
32 comparable investments in software and medical technology (Gaddy et al. 2017), which led to a retreat
33 from investors from hardware technologies required for renewable energy generation and storage to
34 software based technologies and demand-side solutions (Bumpus and Comello 2017).

35 The preference for particular types of investments in renewable energy technologies depends on
36 investors attitude to risk (Mazzucato and Semieniuk 2018). Some investors invest in only one
37 technology, others may spread their investments, or invest predominantly in high-risk technologies. The
38 distribution of different types of investors will affect whether finance goes to support deployment of
39 new high-risk technologies, or diffusion of more mature, less-risky technologies characterized by
40 incremental innovations. The role of finance in directing investment is further discussed in Chapter 15,
41 Section 15.6.2.

42 **16.2.3.3 Internationalization of green technological change**

43 A unilateral effort to reduce emission (via a combination of climate, industrial and trade policies) in a
44 coalition of regions that are technology leaders will reduce cost of clean technologies, which will induce
45 emission reduction in the countries outside the coalition (Di Maria and Smulders 2005; Di Maria and
46 van der Werf 2008; van den Bijgaart 2017; Golombek and Hoel 2004; Hémous 2016). The literature

1 suggests various mechanisms leading to this result. Di Maria and van der Werf (2008) argues that the
2 effort to reduce emission in one region reduces global demand for dirty good. This will redirect global
3 innovation towards clean technologies, leading to drop in cost of clean production in every region.

4 The model in Hemous (2016) predict that the coalition could induce acceleration of clean technological
5 change with a mix of carbon tax, clean R&D subsidies and trade policies in that region leading to
6 reduction of cost of clean production inside the coalition. Export of goods produced with clean
7 technologies to a region outside the coalition reduces demand for dirty good in that region. In the model
8 by van den Bijgaart (2017) local advancements of clean technologies by a coalition with strong R&D
9 potential are imitated outside the coalition. Furthermore, advancements of clean technologies will
10 incentivise future clean R&D outside the coalition due to intertemporal knowledge spillovers. In
11 Golombek and Hoel (2004) increase in environmental concern in one region increases abatement R&D
12 in that region. Part of this knowledge spills over to other regions, increasing their incentive to increase
13 abatement too, providing the latter regions did not invest in abatement before.

14 However, this chain breaks if the regions that are behind technological frontier (i.e., technological
15 followers) are not able to absorb the solutions developed by regions at the frontier. New technologies
16 might fail due to deficiencies of political, commercial, industrial, and financial institutions, which we
17 list in table 16.4. For instance, countries might not benefit fully from international knowledge spillover
18 due to insufficient domestic R&D investment, since local knowledge is needed to determine the
19 appropriateness of technologies for the local market, adapting them, installing and using effectively
20 (Gruebler et al. 2012). From the policy perspective this implies that simple transfer of technologies
21 could be insufficient to guarantee adoption of new technologies (Gruebler et al. 2012).

22
23 **Table 16.4 Examples of institutional deficiencies preventing deployment of new technologies in countries**
24 **behind technological frontier.**

Institutions	Examples of deficiencies	Literature reference
Industrial	Inability to benefit fully from international knowledge spillover due to insufficient domestic R&D investment	(Mancusi 2008; Unel 2008; Gruebler et al. 2012)
Commercial	Insufficient experience with the organization and management of large-scale enterprise	(Abramovitz 1986; Aghion et al. 2005)
Political	Vested interests and customary relations among firms and between employers and employees	(Olson 1982; Abramovitz 1986).
Financial	Financial markets incapable of mobilizing capital for individual firms at large scale	(Abramovitz 1986; Aghion et al. 2005)

25
26 Research relying on patent citations has indicated that Foreign Direct Investment (FDI) is a mechanism
27 for firms to both contribute to the recipient country's innovation output as well as benefitting from the
28 recipient country both in industrialized countries (Branstetter 2006) and in developing countries
29 (Newman et al. 2015). However, insights specific for energy or climate change mitigation areas are not
30 available, nor is there much information about how other innovation metrics may react to FDI.

31 Finally, technologies could be not efficient in developing countries even if they are efficient in countries
32 at the technological frontier. For instance, technologies that are highly capital intensive and labour
33 saving will be efficient only in countries where costs of capital are low and costs of labour are high.
34 Similarly, technologies which require large number of skilled labour will be more competitive in a

1 country where skilled labour is abundant (and hence cheap) than where it is scarce (Basu and Weil
2 1998; Caselli and Coleman 2006).

3 **16.2.3.4 Market failures in directing technological change**

4 Market forces alone cannot deliver Pareto optimal (i.e. socially efficient) due to at least two types of
5 externalities: GHG emissions that cause climate damage and knowledge spillovers that benefit firms
6 other than the inventor. Nordhaus (2011) argues that these two problems would have to be tackled
7 separately: once the favourable intellectual property right regimes (i.e. the laws or rules or regulation
8 on protection and enforcement) are in place, a price on carbon that corrects the emission externality is
9 sufficient to induce optimal level of green technological change. Acemoglu et al. (2012) demonstrates
10 that subsidizing clean technologies (and not dirty ones) is also necessary to break the lock-in of dirty
11 technological change. Recommendations for technical changes often are based on climate
12 considerations only and neglect secondary externalities and environmental costs of technology choices
13 (such as loss of biodiversity due to inappropriate scale-up of bioenergy use). The scale of adverse side
14 effects and co-benefits varies considerably between low-carbon technologies in the energy sector
15 (Luderer et al. 2019).

16

17 **16.2.4 Representation of the innovation process in modelled decarbonization pathways**

18 A variety of models are used to generate climate mitigation pathways, compatible with 2°C and well
19 below 2°C targets. These include Integrated Assessment Models (IAMs), energy system models,
20 computable general equilibrium models and agent based models. They range from global (Chapter 3)
21 to national models and include both top-down and bottom-up approaches (Chapter 4). Innovation in
22 energy technologies, which comprises the development and diffusion of low-, zero- and negative-
23 carbon energy options, but also investments to increase energy efficiency, is a key driver of emissions
24 reductions in model-based scenarios.

25 **16.2.4.1 Technology cost development**

26 Assumptions on energy technology cost developments are one of the factors that determine the speed
27 and magnitude of the deployment in climate-energy-economy models. The modelling is informed by
28 the empirical literature estimating rates of cost reductions for energy technologies. A first strand of
29 literature relies on the extrapolation of historical data, assuming that costs decrease either as a power
30 law of cumulative production, exponentially with time (Nagy et al. 2013) or as a function of technical
31 performance metrics (Koh and Magee 2008). Another approach relies on expert estimates of how future
32 costs will evolve, including expert elicitations (Verdolini et al. 2018).

33 In these models, technology costs may evolve exogenously or endogenously (Krey et al. 2019; Mercure
34 et al. 2016). In the first case, technology costs are assumed to vary over time at some predefined rate,
35 generally extrapolated from past observed patterns or based on expert estimates. This formulation of
36 cost dynamics generally underestimates future costs (Meng et al. 2021) as, among other things, it does
37 not capture any policy-induced carbon-saving technological change or any spillover arising from the
38 accumulation of national and international knowledge (Section 16.2.2 and 16.2.3) or positive
39 macroeconomics effects of a transition (Karkatsoulis et al. 2016). The influence of cost and diffusion
40 assumptions may be evaluated through sensitivity analysis. In the second case, costs are a function of
41 a choice variable within the model. For instance, technology costs decrease as a function of either
42 cumulative installed capacity (learning-by-doing) (Seebregts et al. 1998; Kypreos and Bahn 2003) or
43 R&D investments or spillovers from other sectors and countries.

44 One factor in this ‘learning-by-researching’ is applied to a wide range of energy technologies but also
45 to model improvements in the efficiency of energy use (Goulder and Schneider 1999; Popp 2004). More
46 complex formulations include two-factor learning processes (see Section 16.2.2.1) (Criqui et al. 2015;

1 Emmerling et al. 2016; Paroussos et al. 2020), multi-factor learning curves (Kahouli 2011; Yu et al.
2 2011), or other drivers of cost reductions such as economies of scale and markets (Elia et al. 2021). The
3 application of two-factor learning curves to model energy technology costs is often constrained by the
4 lack of information on public and/or private energy R&D investments in many fast-developing and
5 developing countries (Verdolini et al. 2018). The approach used to model energy technology costs
6 reductions varies across technologies, even within the same model, depending on the availability of
7 data and/or the level of maturity. Less mature technologies generally depend highly on learning-by-
8 research, whereas learning-by-doing dominates in more mature technologies (Jamash 2007).

9 In addition to learning, knowledge spillover effects are also integrated in climate-energy-economy
10 models to reflect the fact that innovation in a given country depends also on knowledge generated
11 elsewhere (Fragkiadakis et al. 2020; Emmerling et al. 2016). Models with a more detailed representation
12 of sectors (Paroussos et al. 2020) can use spillover matrices to include bilateral spillovers and compute
13 learning rates that depend on the human capital stock and the regional and/or sectoral absorption rates
14 (Fragkiadakis et al. 2020). Accounting for knowledge spillovers in the EU for PV, wind turbines, EVs,
15 biofuels, industry materials, batteries and advanced heating and cooking appliances can lead to the
16 following results in a decarbonization scenario over the period 2020–2050 as compared to the reference
17 scenario: an increase of 1.0–1.4% in GDP, 2.1–2.3% in investment, and 0.2–0.4% in employment by
18 clean energy technologies (Paroussos et al. 2017). When comparing two possible EU transition
19 strategies - being a first-mover with strong unilateral emission reduction strategy until 2030 versus
20 postponing action for the period after 2030 - endogenous technical progress in the green technologies
21 sector can alleviate most of the negative effects of pioneering low-carbon transformation associated
22 with loss of competitiveness and carbon leakage (Karkatsoulis et al. 2016).

23 **16.2.4.2 Technology deployment and diffusion**

24 To simulate possible paths of energy technology diffusion for different decarbonisation targets, models
25 rely on assumptions about the cost of a given technology cost relative to the costs of other technologies
26 and its ability to supply the energy demand under the relevant energy system and physical constraints.
27 These assumptions include, for example, considerations regarding renewable intermittency, inertia on
28 technology lifetime (for instance, under less stringent temperature scenarios early retirement of fossil
29 plants does not take place), distribution, capacity and market growth constraints, as well as the presence
30 of policies. These factors change the relative price of technologies. Furthermore, technological diffusion
31 in one country is also influenced by technology advancements in other regions (Kriegler et al. 2015).

32 Technology diffusion may also be strongly influenced, either positively or negatively, by a number of
33 non-cost, non-technological barriers or enablers regarding behaviours, society and institutions
34 (Knobloch and Mercure 2016). These include network or infrastructure externalities, the co-evolution of
35 technology clusters over time (“path dependence”), the risk-aversion of users, personal preferences and
36 perceptions and lack of adequate institutional framework which may negatively influence the speed of
37 (low-carbon) technological innovation and diffusion, heterogeneous agents with different preferences
38 or expectations, multi-objectives and/or competitiveness advantages and uncertainty around the
39 presence and the level of environmental policies and institutional and administrative barriers (Iyer et al.
40 2015; Baker et al. 2015; Marangoni and Tavoni 2014; van Sluisveld et al. 2020; Napp et al. 2017;
41 Biresselioglu et al. 2020). These types of barriers to technology diffusion are currently not explicitly
42 detailed in most of the climate-energy-economy models. Rather, they are accounted for in models
43 through scenario narratives, such as the ones in the Shared Socioeconomic Pathways (Riahi et al. 2017),
44 in which assumptions about technology adoption are spanned over a plausible range of values.
45 Complementary methods are increasingly used to explore their importance in future scenarios
46 (Turnheim et al. 2015; Gambhir et al. 2019; Trutnevyte et al. 2019; Doukas et al. 2018; Geels et al.
47 2016). It takes a very complex modelling framework to include all aspects affecting technology cost
48 reductions and technology diffusion, such as heterogeneous agents (Lamperti et al. 2020), regional

1 labour costs (Skelton et al. 2020), materials cost and trade and perfect foresight multi-objective
2 optimization (Aleluia Reis et al. 2021). So far, no model can account for all these interactions
3 simultaneously.

4 Another key aspect of decarbonization regards issues of acceptability and social inclusion in decision-
5 making. Participatory processes involving stakeholders can be implemented using several methods to
6 incorporate qualitative elements in model-based scenarios on future change (Doukas and Nikas 2020;
7 van Vliet et al. 2010; Nikas et al. 2017, 2018; van der Voorn et al. 2020).

8 **16.2.4.3 Implications for the modelling of technical change in decarbonization pathways**

9 Although the debate is still ongoing, preliminary conclusions indicate that integrated assessment
10 models tend to underestimate innovation on energy supply but overestimate the contributions by energy
11 efficiency (IPCC 2018b). Scenarios emerging from cost-optimal climate-energy-economy models are
12 too pessimistic, especially in the case of rapidly changing technologies such as wind and batteries in
13 the past decade. Conversely, they tend to be too optimistic regarding the timing of action, or the availability
14 of a given technology and its speed of diffusion (Shiraki and Sugiyama 2020). Furthermore, some
15 technological and economic transformations may emerge as technically feasible from IAMs, but are not
16 realistic if taking into account political economy, international politics, human behaviours, and cultural
17 factors (Bosetti 2021).

18 There is a range of projected energy technology supply costs included in the AR6 Scenario Database
19 (Box 16.1). Variations of costs over time and across scenarios are within ranges comparable to those
20 observed in recent years. Conversely, model results show that limiting warming to 2°C or 1.5°C will
21 require faster diffusion of installed capacity of low-carbon energy options and a rapid phase out of
22 fossil-based options. This points to the importance of focusing on overcoming real-life barriers to
23 technology deployment.

24

25 **START BOX 16.1 HERE**

26 **Box 16.1 Comparing observed energy technology costs and deployment rates with projections** 27 **from AR6 low-carbon pathways**

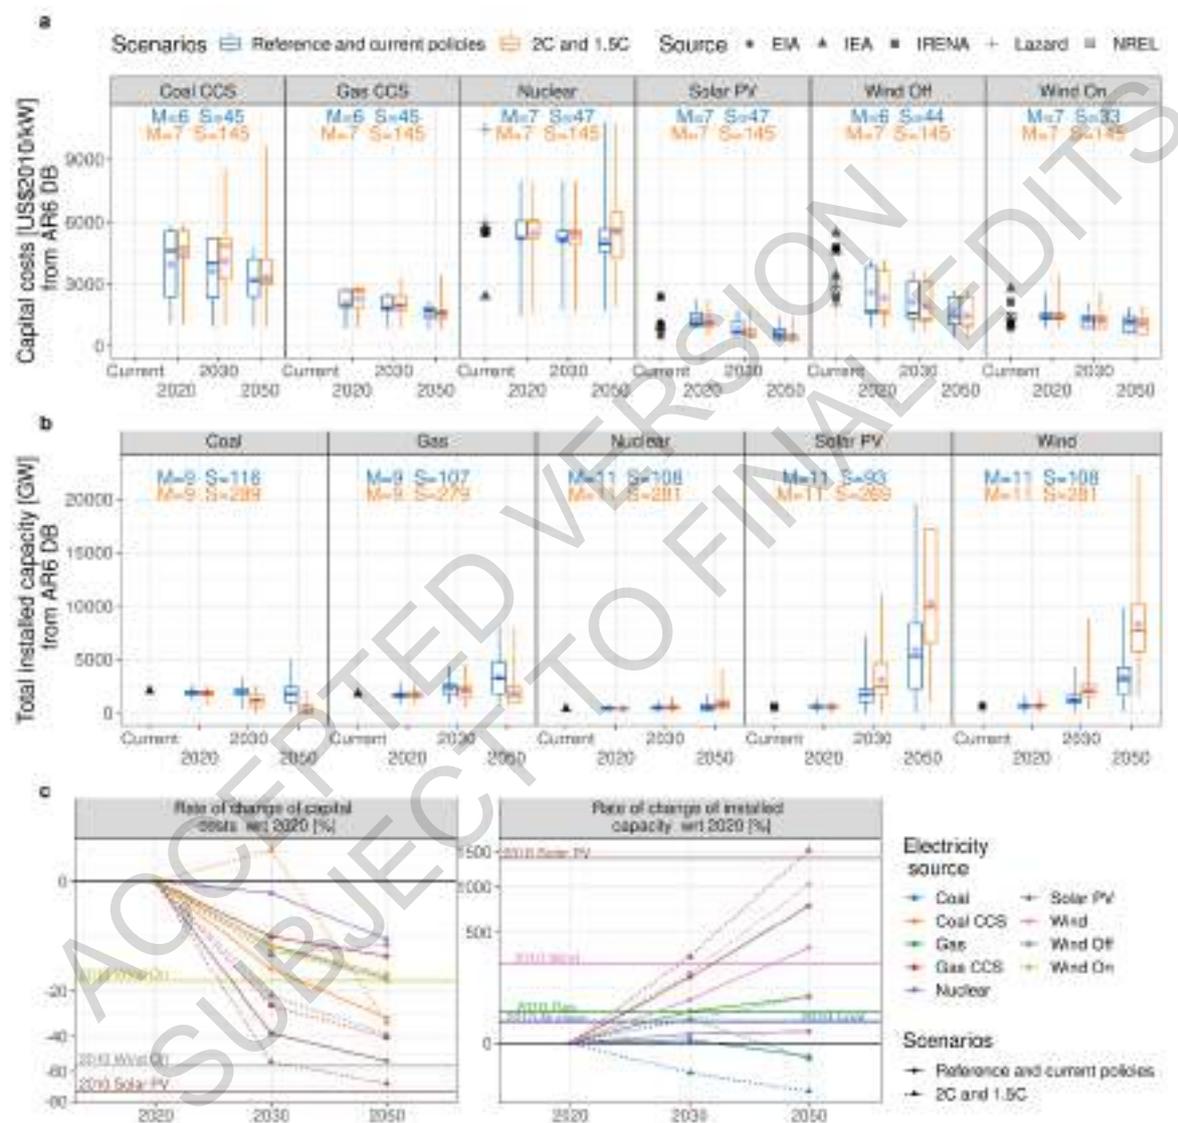

28 Currently observed costs and deployment for electricity supply technologies from a variety of sources
29 are compared with projections from two different sets of scenarios contained in the AR6 Scenario
30 database: 1) reference and current policies including NDCs and 2) 2°C and well-below 2°C (AR6 model
31 database). Global aggregate costs are shown for the following technologies: Coal with CCS, Gas with
32 CCS, Nuclear, Solar PV, Onshore and Offshore Wind.

33 The decrease in forecasted capital costs is not large compared to current capital costs for most
34 technologies, and does not differ much between the two scenarios (Box 16.1, Figure 1a). For Wind
35 offshore some of the models are more optimistic than the current reality (Timilsina 2020). Several
36 sources of current solar PV costs report values that are at the low end of the AR6 model scenario
37 database. By 2050, the median technology cost forecasts decrease by between 5% for nuclear and 45-
38 52% for solar (Box 16.1, Figure 1c).

39 Median values of renewables installed capacity increase with respect to 2020 capacity in “*current*
40 *policies*” scenarios (Box 16.1, Figure 1b), where energy and climate policies are implemented in line
41 with the current NDCs. More stringent targets (2°C) are achieved through a higher deployment of
42 renewable technologies: by 2050 solar (wind) capacity is estimated to increase by a factor of 15 (10)
43 (Box 16.1, Figure 1c). This is accompanied by an almost complete phase out of coal (-87%). The
44 percentage of median changes in installed capacity in the current policies scenarios is within comparable

1 ranges of that observed in the last decade. In the case of the 2°C and well-below 2°C scenarios, capacity
 2 installed is higher for renewable technologies and nuclear, and lower for fossil-based technologies (Box
 3 16.1, Figure 1c).

4 The higher deployment in 2°C scenarios cannot be explained solely as a result of technology cost
 5 dynamics. In IAMs, technology deployment is also governed by system constraints that characterize
 6 both scenarios, e.g. the flexibility of the energy system, the availability of storage technologies. From a
 7 modelling point of view, implementing more stringent climate policies to meet the 2°C targets forces
 8 models to find solutions, even if costly, to meet those intermittency and flexibility constraints and
 9 temperature target constraints.

10

7 **16.3 A systemic view of technological innovation processes**

8 The innovation process, which consists of a set of sequential phases (Section 16.2.1), is often simplified
9 to a linear process. Yet, it is now well understood that it is also characterised by numerous kinds of
10 interactions and feedbacks between the domains of knowledge generation, knowledge translation and
11 application, and knowledge use (Kline and Rosenberg 1986). Furthermore, it is not just invention that
12 leads to technological change but the cumulative contribution of incremental innovations over time can
13 be very significant (Kline and Rosenberg 1986). Innovations can come not just from formal R&D but
14 also sources such as production engineers and the shop floor (Freeman 1995a; Kline and Rosenberg
15 1986).

16 This section reviews the literature focusing on innovation as a systemic process. This now predominant
17 view enriches the understanding of innovation as presented in section 16.2; it conceptualizes innovation
18 as the result of actions by, and interactions among, a large set of actors, whose activities are shaped by,
19 and shape, the context in which they operate and the user group with which they are engaging. This
20 section aligns with the discussion of socio-technical transitions (see Chapter 1 Section 1.7.3, the
21 Supplementary Material in Chapter 5, and Cross-Chapter Box 12 in this chapter).

23 **16.3.1 Frameworks for analysing technological innovation processes**

24 The resulting overarching framework that is commonly used in the innovation scholarship and even
25 policy analyses is termed as “innovation system”, where the key constituents of the systems are actors,
26 their interactions, and the institutional landscape, including formal rules, such as laws, and informal
27 restraints, such as culture and codes of conduct, that govern the behaviour of the actors (North 1991).

28 One application of this framework is that of *national innovation systems (NIS)*, which highlights the
29 importance of national and regional relationships for determining the technological and industrial
30 capabilities and development of a country (Nelson 1993; Lundvall 1992; Freeman 1995a). Nelson
31 (1993) and Freeman (Freeman 1995a) highlight the role of institutions that determine the innovative
32 performance of national firms as way to understand differences across countries, while Lundvall (1992)
33 focuses on the “elements and relationships which interact in the production, diffusion and use of new,
34 and economically useful, knowledge”, i.e., notions of interactive learning, in which user-producer
35 relationships are particularly important (Lundvall 1988). Building on this, various other applications of
36 the “innovation systems” framework have emerged in the literature.

37 *Technological Innovation systems (TIS)*, with technology or set of technologies (more narrowly or
38 broadly defined in different cases) as the unit of analysis and focus on explaining what accelerates or
39 hinders their development and diffusion. Carlsson and Stankiewicz (1991) define a technological
40 system as “a dynamic network of agents interacting in a specific economic/ industrial area under a
41 particular institutional infrastructure and involved in the generation, diffusion, and utilisation of
42 technology.” More recent work takes a “functional approach” to TIS (Bergek et al. 2008; Hekkert et al.
43 2007), which was later expanded with explanations of how some of the sectoral, geographical and
44 political dimensions intersect with technology innovation systems (Bergek et al. 2015; Quitzow 2015).

1 *Sectoral innovation systems (SIS)*: based on the understanding that the constellation of relevant actors
 2 and institutions will vary across industrial sectors, with each sector operating under a different
 3 technological regime and under different competitive or market conditions. A sectoral innovation, thus,
 4 can be defined as “that system (group) of firms active in developing and making a sector's products and
 5 in generating and utilising a sector's technologies” (Breschi and Malerba 1997).

6 *Regional and Global innovation systems (RIS, GIS)*, recognising that the many innovation processes
 7 have a spatial dimension, where the development of system resources such as knowledge, market
 8 access, financial investment, and technology legitimacy may well draw on actors, networks, and
 9 institutions within a region (Cooke et al. 1997). In other cases, the distribution of many innovation
 10 processes are highly internationalised and therefore outside specific territorial boundaries (Binz and
 11 Truffer 2017). Importantly, Binz and Truffer (2017) note that the GIS framework “differentiates
 12 between an industry’s dominant innovation mode... and the economic system of valuation in which
 13 markets for the innovation are constructed.”

14 *Mission-oriented innovation systems (MIS)*, whose relevance comes into focus with the move towards
 15 mission-oriented programs as part of the increasing innovation policy efforts to address societal
 16 challenges. Accordingly, an MIS is seen as consisting of “networks of agents and sets of institutions
 17 that contribute to the development and diffusion of innovative solutions with the aim to define, pursue
 18 and complete a societal mission” (Hekkert et al. 2020).

19 Notably the innovation systems approach has been used in a number of climate-relevant areas such as
 20 agriculture (Echeverría 1998; Klerkx et al. 2012; Horton and Mackay 2003; Brooks and Loevinsohn
 21 2011), energy (Sagar and Holdren 2002; OECD 2006; Gallagher et al. 2012; Wieczorek et al. 2013;
 22 Mignon and Bergek 2016; Darmani et al. 2014), industry (Koasidis et al. 2020b) and transport (Koasidis
 23 et al. 2020a), and sustainable development (Clark et al. 2016; Bryden and Gezelius 2017; Anadon et al.
 24 2016b; Nikas et al. 2020).

25 A number of functions can be used to understand and characterise the performance of technological
 26 innovation systems (Hekkert et al. 2007; Bergek et al. 2008). The most common functions are in Table
 27 16.5.

28

29 **Table 16.5 Functions that the literature identified as key for well-performing technological innovation**
 30 **systems (based on Hekkert et al (2007) and Bergek et al (2008))**

Functions	Description
Entrepreneurial activities and experimentation	Entrepreneurial activities and experimentation for translating new knowledge and/or market opportunities into real-world application
Knowledge development	Knowledge development includes both “learning-by-searching” and “learning-by-doing”
Knowledge diffusion	Knowledge diffusion through networks, both among members of a community (e.g., scientific researchers) and across communities (e.g., universities, business, policy, and users).
Guidance of search	Guidance of search directs the investments in innovation in consonance with signals from the market, firms or government
Market formation	Market formation through customers or government policy is necessary to allow new technologies to compete with incumbent technologies
Resource mobilisation	Resource mobilisation pertains to the basic inputs – human and financial capital – to the innovation process

Creation of legitimacy/counteract resistance to change	Creation of legitimacy or counteracting resistance to change, through activities that allow a new technology to become accepted by users, often despite opposition by incumbent interests
Development of external economies	Development of external economies, or the degree to which other interests benefit from the new technology

1

2 Evidence from empirical case studies indicates that all the above functions are important and that they
3 interact with one another (Hekkert and Negro 2009). The approach therefore serves as both a rationale
4 for and a guide to innovation policy (Bergek et al. 2010).

5 A much-used, complementary systemic framework is the multilevel perspective (MLP) (Geels 2002),
6 which focuses mainly on the diffusion of technologies in relation to incumbent technologies in their
7 sector and the overall economy. A key point of MLP is that new technologies need to establish
8 themselves in a stable ‘socio-technical regime’ and are therefore generally at a disadvantage, not just
9 because their low technological maturity, but also because of an unwelcoming system. The MLP
10 highlights that the uptake of technologies in society is an evolutionary process, which can be best
11 understood as a combination of “variation, selection and retention” as well as “unfolding and
12 reconfiguration” (Geels 2002). Thus new technologies in their early stages need to be selected and
13 supported at the micro-level by niche markets, possibly through a directed process that has been termed
14 “strategic niche management” (Kemp et al. 1998). As at the macro landscape level pressures on
15 incumbent regimes mount, and those regimes destabilise, the niche technologies get a chance to get
16 established in a new socio-technical regime, which allows these technologies to grow and stabilise,
17 shaping a changed or sometimes radically renewed socio-technical regime. The MLP takes a systematic
18 and comprehensive view about how to nurture and shape technological transitions by understanding
19 them as evolutionary, multi-directional and cumulative socio-technical process playing out at multiple
20 levels over time with a concomitant expansion in the scale and scope of the transition (Elzen et al. 2004;
21 Geels 2005b). There have been numerous studies that draw on the MLP (van Bree et al. 2010; Geels et
22 al. 2017; Geels 2012) to understand different aspects of climate technology innovation and diffusion.

23 Systemic analyses of innovation have predominantly focused on industrialised countries. There have
24 been some efforts to use the innovation systems lens for the developing country context (Jacobsson and
25 Bergek 2006; Lundvall et al. 2009; Altenburg 2009; Choi and Zo 2019; Tigabu 2018; Tigabu et al.
26 2015) and specific suggestions on ways for developing countries to strengthening their innovation
27 systems (e.g., by universities taking on a “developmental” role (Arocena et al. 2015) or industry
28 associations acting as intermediaries to build institutional capacities (Watkins et al. 2015; Khan et al.
29 2020), including specifically for addressing climate challenges (Sagar et al. 2009; Ockwell and Byrne
30 2016). But the conditions in developing countries are quite different, leading to suggestions that
31 different theoretical conceptualisations of the innovation systems approach may be needed for these
32 countries (Arocena and Sutz 2020), although a system perspective would still be appropriate (Boodoo
33 et al. 2018).

34

35 **16.3.2 Identifying systemic failures to innovation in climate-related technologies**

36 Traditional perspectives on innovation policy were mostly science-driven, and focused on strengthening
37 invention and its translation into application in a narrow sense, and a second main traditional perspective
38 on innovation policy was focused on correcting for ‘market failures’ (covered in Section 16.2) (Weber
39 and Truffer 2017). The more recent understanding of, and shift of focus to, the systemic nature on the
40 innovation and diffusion of technologies has implications for innovation policy since innovation
41 outcomes depend not just on inputs such as R&D but much more on the functioning of the overall
42 innovation system (see previous section and Section 16.4). Policies can therefore be directed at

1 innovation systems components and processes that need the greatest attention or support. This may
 2 include, for example, strengthening the capabilities of weak actors and improving interactions between
 3 actors (Jacobsson et al. 2017; Weber and Truffer 2017). At the same time, a systemic perspective also
 4 brings into sharp relief the notion of ‘system failures’ (Weber and Truffer 2017).

5 Systemic failures include infrastructural failures; hard (e.g., laws, regulation) and soft (e.g., culture,
 6 social norms) institutional failures; interaction failures (strong and weak network failures); capability
 7 failures relating to firms and other actors; lock-in; and directional, reflexivity, and coordination failures
 8 (Klein Woolthuis et al. 2005; Chaminade and Esquist 2010; Weber and Rohracher 2012; Wieczorek
 9 and Hekkert 2012; Negro et al. 2012). By far most of the literature that unpacks such failures and
 10 explores ways to overcome them is on energy-related innovation policy. For example, Table 16.6
 11 summarizes a meta-study (Negro et al. 2012) that examined cases of renewable energy technologies
 12 trying to disrupt incumbents across a range of countries to understand the roles, and relative importance,
 13 of the ‘systemic problems’ highlighted in Section 16.3.1.

14

15 **Table 16.6 Examination of systemic problems preventing renewable energy technologies from reaching**
 16 **their potential, including number of case studies in which the particular ‘systemic problem’ was**
 17 **identified** Source: (Negro et al. 2012).

Systemic problems	Empirical sub-categories	No. of cases
Hard institutions	<ul style="list-style-type: none"> - ‘Stop and go policy’: lack of continuity and long-term regulations; inconsistent policy and existing laws and regulations - ‘Attention shift’: policy makers only support technologies if they contribute to the solving of a current problem - ‘Misalignment’ between policies on sector level such as agriculture, waste, and on governmental levels, i.e. EU, national, regional level, etc. - ‘Valley of Death’: lack of subsidies, feed-in tariffs, tax exemption, laws, emission regulations, venture capital to move technology from experimental phase towards commercialisation phase 	51
Market structures	<ul style="list-style-type: none"> - Large-scale criteria - Incremental/near-to-market innovation - Incumbent’s dominance 	30
Soft institutions	<ul style="list-style-type: none"> - Lack of legitimacy - Different actors opposing change 	28
Capabilities/capacities	<ul style="list-style-type: none"> - Lack of technological knowledge of policy makers and engineers - Lack of ability of entrepreneurs to pack together, to formulate clear message, to lobby to the government - Lack of users to formulate demand - Lack of skilled staff 	19
Knowledge infrastructure	<ul style="list-style-type: none"> - Wrong focus or not specific courses at universities knowledge institutes - Gap/Misalignment between knowledge produce at universities and what needed in practice 	16

Too weak interactions	- Individualistic entrepreneurs - No networks, no platforms - Lack of knowledge diffusion between actors - Lack of attention for learning-by-doing	13
Too strong interactions	- Strong dependence on government action or dominant partners (incumbents) - Networks allows no access to new entrants	8
Physical infrastructure	- No access to existing electricity or gas grid for RETs - No decentralised, small-scale grid - No refill infrastructure for biofuels, ABG, H2, biogas	2

1 Depending on the sector, specific technology characteristics, and national and regional context, the
 2 relevance of these systemic problems varies (Trianni et al. 2013; Bauer et al. 2017; Wesseling and Van
 3 der Vooren 2017; Koasidis et al. 2020b,a), suggesting that the innovation policy mix has to be tailor-
 4 made to respond to the diversity of systemic failures (Rogge et al. 2017). An illustration of how such
 5 systemic failures have been addressed is given in Box 16.2, which shows how the Indian government
 6 designed its standards and labelling programme for energy-efficient air conditioners and refrigerators.
 7 The success of this program resulted from the careful attention to bring on board and coordinate the
 8 relevant actors and resources, the design of the standards, and ensuring effective administration and
 9 enforcement of the standards (Malhotra et al. 2021).

10

11 **START BOX 16.2 HERE**12 **Box 16.2: Standards and Labelling (S&L) for energy efficient refrigerators and air conditioners**
13 **in India²**

14 Energy efficiency is often characterised as a “low-hanging fruit” for reducing energy use. However,
 15 systemic failures such as lack of access to capital, hidden costs of implementation, and imperfect
 16 information can result in low investments into adoption and innovation in energy efficiency measures
 17 (Sorrell et al. 2004). To address such barriers, India’s governmental Bureau of Energy Efficiency (BEE)
 18 introduced the Standards and Labelling (S&L) programme for promotion of innovation in energy
 19 efficient appliances in 2006 (Sundaramoorthy and Walia 2017). While context-dependent, the
 20 programme design, policies and scale-up contain lessons for addressing systemic failures elsewhere too.

21 *Program design and addressal of early systemic barriers*

22 To design the S&L program, BEE drew on the international experiences and technical expertise of the
 23 Collaborative Labelling and Appliance Standards Program (CLASP) – a non-profit organisation that
 24 provides technical and policy support to governments in implementing S&L programs. For example,
 25 since there was no data on the efficiency of appliances in the Indian market, CLASP assisted with early
 26 data collection efforts, resulting in a focus on refrigerators and air conditioners (ACs) (McNeil et al.
 27 2008).

FOOTNOTE ² This section draws on “The role of capacity-building in policies for climate change mitigation and sustainable development: The case of energy efficiency in India” (Malhotra et al. 2021)

1 Besides drawing from international knowledge, the involvement of manufacturers, testing laboratories,
2 and customers was crucial for the functioning of the innovation system.

3 To involve manufacturers, BEE employed three strategies to set the standards at an ambitious yet
4 acceptable level. First, BEE enlisted IIT Delhi (a public technical university) to engage with
5 manufacturers and to demonstrate cost-effective designs of energy-efficient appliances. Second, BEE
6 agreed to make the standards voluntary from 2006 to 2010. In return, the manufacturers agreed to
7 mandatory and progressively more stringent standards starting in 2010. Third, BEE established a multi-
8 stakeholder committee with representation from BEE, the Bureau of Indian Standards, appliance
9 manufacturers, test laboratories, independent experts, and consumer groups (Jairaj et al. 2016) to ensure
10 that adequately stringent standards are negotiated every two years.

11 At this time, India had virtually no capacity for independent testing of appliances. Here too, BEE used
12 multiple approaches towards creating the actors and resources needed for the innovation system to
13 function. First, BEE funded the Central Power Research Institute (CPRI) – a national laboratory for
14 applied research, testing and certification of electrical equipment – to set up refrigerator and AC testing
15 facilities. Second, they invited bids from private laboratories, thus creating a demand for testing
16 facilities. Third, BEE developed testing protocols in partnership with universities. Australian standards
17 for testing frost-free refrigerators were adopted until local standards were developed. Thus, once the
18 testing laboratories, protocols and benchmark prices for testing were in place, the appliance
19 manufacturers could employ their services.

20 Finally, a customer outreach program was conducted from 2006 to 2008 to inform customers regarding
21 energy efficient appliances, to enable them to interpret the labels correctly, and to understand their
22 purchase decisions and information sources (Joshi et al. 2019; Jain et al. 2018). BEE initiated a capacity
23 building program for retailers to be an information source for costumers. A comprehensive document
24 with details of different models and labels was provided to retailers, together with a condensed booklet
25 to be shared with customers.

26 *Adapting policies to technologies and local context*

27 While many of India's standards and testing protocols were based on international standards, they
28 needed to be adapted to the Indian context. For example, because of higher temperatures in India, the
29 reference outside temperature of 32°C for refrigerators was changed to 36°C.

30 AC testing protocols also had to be adapted because of the emergence of inverter-based ACs. Existing
31 testing done only at a single temperature did not value inverter-based ACs' better average performance
32 as compared to fixed-speed ACs over a range of temperatures. Thus, the Indian Seasonal Energy
33 Efficiency Ratio (ISEER) was developed for Indian temperature conditions in 2015 by studying ISO
34 standards and through consultations with manufacturers (Mukherjee et al. 2020).

35 These measures had multiple effects on technological change. As a result of stringent standards, India
36 has some of the most efficient refrigerators globally. In the case of ACs, the ISEER accelerated
37 technological change by favouring inverter-based ACs over fixed-speed ACs, driving down their costs
38 and increasing their market shares (BEE 2020).

39 *Scaling up policies for market transformation*

40 As the S&L program was expanded, BEE took measures to standardise, codify and automate it. For
41 example, to process a high volume of applications for labels efficiently, an online application portal
42 with objective and transparent certification criteria was created. This gave certainty to the
43 manufacturers, enabling diversity and faster diffusion of energy-efficient appliances. Thus by 2019, the
44 program expanded to cover thousands of products across 23 appliance types (BEE 2020).

1 Besides issuing labels, the enforcement of standards also needed to be scaled up efficiently. BEE
2 developed protocols for randomly sampling appliances for testing. Manufacturers were given a fixed
3 period to rectify products that did not meet the standards, failing which they would be penalised and
4 the test results would be made public.

5 **END BOX 16.2 HERE**

6

7 **16.3.3 Indicators for technological innovation**

8 Assessing the state of technological innovation helps understanding how current efforts and policies are
9 doing in relation to stated objectives and how we might design policies in order to do better.

10 Traditionally, input measures such as RD&D investments and output measures such as scientific
11 publication and patents were used to characterise innovation activities (Freeman and Soete 2009), partly
12 because of the successes of specialised R&D efforts (Freeman 1995a), the predominant linear model of
13 innovation, and because such measures can (relatively) easily obtained and compared. In the realm of
14 energy-related innovation, RD&D investments remains the single most-used indicator to measure inputs
15 into the innovation process (Box 16.3). Patents counts are a widely used indicator of the outputs of the
16 innovation process, especially because they are detailed enough to provide information on specific
17 adaptation and mitigation technologies. Mitigation and adaptation technologies have their own
18 classification (Y02) with the European Patent Office (EPO) (Veefkind et al. 2012; Angelucci et al.
19 2018), which can be complemented with keyword search and manual inspection (Persoon et al. 2020;
20 Surana et al. 2020b). However, using energy-related patents as indicator of innovative activities is
21 complicated by several issues (Haščič and Migotto 2015; Jaffe and de Rassenfosse 2017; de
22 Rassenfosse et al. 2013), including the fact that the scope of what are to be considered climate mitigation
23 inventions is not always clear or straightforward.

24 Conversely, private energy R&D investments and investments by financing firms cannot be precisely
25 assessed for a number of reasons, including limited reporting and the difficulty of singling out energy-
26 related investments. This inability to precisely quantify private investments in energy R&D leads to a
27 patchy understanding of the energy innovation system, and how private energy R&D investments
28 responds to public energy R&D investments. Overall, evidence shows that some of the industrial sectors
29 that are important for meeting climate goals (electricity, agriculture and forestry, mining, oil and gas,
30 and other energy-intensive industrial sectors) are investing relatively small fractions of sales on R&D
31 (*medium evidence, high agreement*) (European Commission 2015; National Science Board 2018;
32 American Energy Innovation Council 2017; Jasmab and Pollitt 2005; Sanyal and Cohen 2009; Jamasb
33 and Pollitt 2008; Gaddy et al. 2017).

34 Financing firms also play an important role in the energy innovation process, but data availability is
35 also limited. The venture capital (VC) financing model, used to overcome the “valley of death” in the
36 biotech and IT space (Frank et al. 1996), has not been as suitable for hardware start-ups in the energy
37 space: for example, the percentage of exit outcomes in clean-tech start-ups was almost half of that in
38 medical start-ups and less than a third of software investments (Gaddy et al. 2017). The current VC
39 model and other private finance do not sufficiently cover the need to demonstrate energy technologies
40 at scale (Mazzucato 2013; Anadón 2012; Nemet et al. 2018). This greater difficulty in reaching the
41 market compared to other sectors may have contributed to a reduction in private equity and venture
42 capital finance for renewable energy technologies after the boom of the late 2000s (Frankfurt School-
43 UNEP Centre/BNEF 2019).

45

Box 16.3 Investments in public energy R&D

1 Public energy R&D investments are a crucial driver of energy technology innovation (Sections 16.2.1.1,
2 16.4.1). Box 16.3, Figure 1 shows the time profile of energy-related RD&D budgets in OECD countries
3 as well as some key events which coincided with developments of spending (IEA 2019). Such data on
4 other countries, in particular developing countries, are not available, although recent evidence suggests
5 that expenditures are increasing there (IEA 2020c). The IEA collected partial data from China and India
6 in the context of Mission Innovation, but this is available only starting in 2014 and thus not included in
7 the Figure.

8 The figure illustrates two points. First, energy-related RD&D has risen slowly in the last 20 years, and
9 is now reaching levels comparable with the peak of energy RD&D investments following the two oil
10 crises. Second, over time there has been a reorientation of the portfolio of funded energy technologies
11 away from nuclear energy. In 2019, around 80% of all public energy RD&D spending was on low-
12 emission technologies – energy efficiency, CCUS, renewables, nuclear, hydrogen, energy storage and
13 cross-cutting issues such as smart grids. A more detailed discussion of the time profile of RD&D
14 spending in IEA countries, including as a share of GDP, are available in (IEA 2020b).

15

16 **Box 16.3, Figure 1 Fraction of public energy RD&D spending by technology over time for IEA (largely**
17 **OECD) countries between 1974 and 2018.**

18 Sources: IEA RD&D Database, 2019 (IEA 2019). (extracted on November 11, 2020).

19 **END BOX 16.3 HERE**

20 Quantitative indicators such as energy-related RD&D spending are insufficient for the assessment of
21 innovation systems (David and Foray 1995): they only provide a partial view into innovation activities,
22 and one that is potentially misleading (Freeman and Soete 2009). Qualitative indicators measuring the
23 more intangible aspects of the innovation process and system are crucial to fully understand the
24 innovation dynamics in a climate or energy technologies or sectors (Gallagher et al. 2006), including in
25 relation to adopting an adaptive learning strategy and supporting learning through demonstration
26 projects (Chan et al. 2017).

27 In Table 16.7, both quantitative and qualitative indicators for systemic innovation are outlined, using
28 clean energy innovation as an illustrative example and drawing on a broad literature base, taking into
29 account both the input-output-outcome classification and its variations (Hu et al. 2018; Freeman and
30 Soete 1997; Sagar and Holdren 2002), combined with the functions of technological innovation systems

1 (Miremadi et al. 2018), while also being cognizant of the specific role of key actors and institutions
2 (Gallagher et al. 2012). A specific assessment of innovation may focus on part of such a list of
3 indicators, depending on what aspect of innovation is being studied, whether the analysis takes a more
4 or less systemic perspective, and the specific technology and geography considered. Similarly,
5 innovation policies may be designed to specifically boost only some of these aspects, depending
6 whether a given country/region is committed to strengthen a given technology or phase.

7 The systemic approach to innovation and transition dynamics (see also Cross-Chapter Box 12 in this
8 chapter) has advanced our understanding of the complexity of the innovation process, pointing to the
9 importance of assessing the efficiency and effectiveness in producing, diffusing and exploiting
10 knowledge (Lundvall 1992), including how the existing stock of knowledge may be recombined and
11 used for new applications (David and Foray 1995). There remains a crucial need for more relevant and
12 comprehensive approaches of assessing innovation (Freeman and Soete 2009; Dziallas and Blind 2019).
13 In the context of climate mitigation, innovation is a means to an end; therefore, there is the need to
14 consider the processes by which the output of innovation (e.g., patents) are translated into real-world
15 outcomes (e.g., deployment of low-carbon technologies) (Freeman and Soete 1997; Sagar and Holdren
16 2002). Currently, a set of quantitative metrics that, collectively, can help get a picture of innovation in
17 a particular energy technology or set of energy technologies is not available. Also the understanding of
18 how to systematically use qualitative indicators to characterise the more intangible aspects of the energy
19 innovation system and to improve front-end innovation decisions is still lacking (Dziallas and Blind
20 2019).

21

1 **Table 16.7 Commonly used quantitative innovation metrics, organized by inputs, outputs and outcomes. Based on (Sagar and Holdren 2002; Gallagher et al. 2006;**
 2 **Hekkert et al. 2007; Gallagher et al. 2012; Miremadi et al. 2018; Hu et al. 2018; Gallagher et al. 2011; Avelino et al. 2019; Gruebler et al. 2012)**

Function	Input indicators	Output indicators	Outcome indicators	Actors	Policies	Structural and systemic indicators

SUBJECT TO FINAL EDITS

1 **16.3.4 Emerging policy perspectives on systemic transformations**

2 Because of the multiple market, government, system, and other failures that are associated with the
3 energy system, a range of policy interventions are usually required to enable the development and
4 introduction of new technologies in the market (Twomey 2012; Jaffe et al. 2005; Bürer and
5 Wüstenhagen 2009; Veugelers 2012; Negro et al. 2012; Weber and Rohrer 2012) and used in what
6 is termed as policy mixes (Rogge and Reichardt 2016; Rogge et al. 2020; Edmondson et al. 2020, 2019)
7 . Empirical research shows that when in the energy and environment space new technologies were
8 developed and introduced in the market, it was usually at least partly as a result of a range of policies
9 that shaped the socio-technical system (Nemet 2019a; Bunn et al. 2014; Rogge and Reichardt 2016;
10 Bergek et al. 2015) (*robust evidence, high agreement*). An example of this systemic and dynamic nature
11 of policies is the 70-year innovation journey of solar PV, covering multiple countries, which is reviewed
12 in Box 16.4.

13

14 **START BOX 16.4 HERE**

15 **Box 16.4 Sources of cost reductions in solar photovoltaics**

16 **No single country persisted in developing solar PV. Five countries each made a distinct**
17 **contribution. Each leader relinquished its lead. The free flow of ideas, people, machines, finance,**
18 **and products across countries explains the success of solar photovoltaics (PV). Barriers to**
19 **knowledge flow delay innovation.**

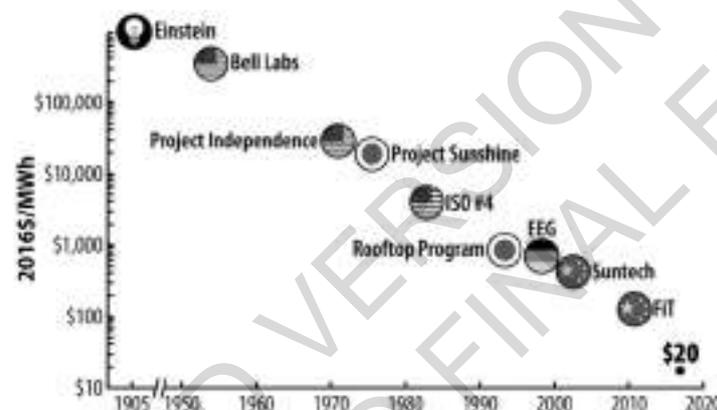

20 Solar PV has attracted interest for decades, and until recently was seen as an intriguing novelty, serving
21 a niche, but widely dismissed as a serious answer to climate change and other social problems associated
22 with energy use. Since AR5, PV has become a substantial global industry—a truly disruptive
23 technology that has generated trade disputes among superpowers, threatened the solvency of large
24 energy companies, and prompted reconsideration of electric utility regulation rooted in the 1930s. More
25 favourably, its continually falling costs and rapid adoption are improving air quality and facilitating
26 climate change mitigation. PV is now so inexpensive that it is important in an expanding set of countries.
27 In 2020, 41 countries, in 6 continents, had installed at least 1GW of solar each (IRENA 2020a).

28 The cost of generating electricity from solar PV is now lower in sunny locations than running existing
29 fossil fuel power plants (Chapter 6) (IEA 2020c). Prices in 2020 were below where even the most
30 optimistic experts expected they would be in 2030.

31 The costs of solar PV modules have fallen by more than a factor of 10,000 since they were first
32 commercialised in 1957. This four orders of magnitude cost reduction from the first commercial
33 application in 1958 until 2018 can be summarised as the result of distinct contributions by the US,
34 Japan, Germany, Australia, and China—in that sequence (Green 2019; Nemet 2019c). As shown in Box
35 16.4 Figure 1, PV improved as the result of:

- 36 1) Scientific contributions in the 1800s and early 1900s, in Europe and the US, that provided a
37 fundamental understanding of the ways that light interacts with molecular structures, leading to the
38 development of the p-n junction to separate electrons and holes (Einstein 1905; Ohl 1941);
- 39 2) A breakthrough at a corporate laboratory in the US in 1954 that made a commercially available PV
40 device available and led to the first substantial orders, by the US Navy in 1957 (Gertner 2013; Ohl
41 1946);
- 42 3) A government R&D and public procurement effort in the 1970s in the US, that entrained skilled
43 scientists and engineers into the effort and stimulated the first commercial production lines (Laird
44 2001; Christensen 1985; Blieden 1999);

- 1 4) Japanese electronic conglomerates, with experience in semiconductors, serving niche markets in the
 2 1980s and in 1994 launching the world's first major rooftop subsidy program, with a declining rebate
 3 schedule and demonstrating there was substantial consumer demand for PV (Kimura and Suzuki
 4 2006);
- 5 5) Germany passing a feed-in tariff in 2000 that quadrupled the market for PV catalysing development
 6 of PV-specific production equipment that automated and scaled PV manufacturing (RESA 2001;
 7 Lauber and Jacobsson 2016);
- 8 6) Chinese entrepreneurs, almost all trained in Australia and using Australian-invented passivated
 9 emitter rear cell technology, building supply chains and factories of gigawatt scale in the 2000s.
 10 China became the world's leading installer of PV from 2013 onward (Helveston and Nahm 2019;
 11 Quitzow 2015).
- 12 7) A cohort of adopters with high willingness to pay, accessing information from neighbours, and
 13 installer firms that learned from their installation experience, as well as that of their competitors to
 14 lower soft costs (Gillingham et al. 2016; Ardani and Margolis 2015).

16 **Box 16.4, Figure 1 Milestones in the development of low-cost solar photovoltaics** (Nemet 2019c)

18 As this evolution makes clear, no individual country persisted in leading the technology and every world
 19 leading firm lost its lead within a few years (Green 2019). Solar followed an overlapping but sequential
 20 process of technology creation, market creation and cost reductions (comparable to emergence, early
 21 adoption, diffusion and stabilisation in Cross-Chapter Box 12 in this chapter). In the technology creation
 22 phase examples of central processes include flows of knowledge from one person to another, between
 23 firms, and between countries as well as US and Japanese R&D funding in the 1970s and early 1980s.
 24 During market creation, PVs modular scale allowed it to serve a variety of niche markets from satellites
 25 in the 1950s to toys in the 1980s, when Germany transformed the industry from niche to mass market
 26 with its subsidy program that began in 2000 and became important for PV in 2004. The dramatic
 27 increase in size combined with its 20-year guaranteed contracts reduced risk for investors and created
 28 confidence in PVs long term growth. Supportive policies also emerged outside Germany, in Spain, Italy,
 29 California, and China, which spread the risk even as national policy support was more volatile. Rapid
 30 and deep cost reductions were made possible by learning-by-doing in the process of operating,
 31 optimising, and combining production equipment; investing and improving each manufacturing line to
 32 gradually scale up to massive sizes and incremental improvements in the PV devices themselves.

33 Central to PV development has been its modularity, which provided two distinct advantages: access to
 34 niche markets, and iterative improvement. Solar has been deployed as a commercial technology across
 35 9 orders of magnitude: from a 1W cell in a calculator to a 1GW plant in the Egyptian desert, and almost
 36 every scale in between. This modular scale enabled PV to serve a sequence of policy-independent niche
 37 markets (such as satellites and telecom applications), which generally increased in size and decreased

1 in willingness to pay, in line with the technology cost reductions. This modular scale also enabled a
2 large number of iterations, such that in 2020 over three billion solar panels have been produced.
3 Compared to, for instance, approximately 1000 nuclear reactors that were ever constructed, a million
4 times more opportunities for learning-by-doing were available to solar PV: to make incremental
5 improvements, to introduce new manufacturing equipment, to optimise that equipment, and to learn
6 from failures. More generally, recent work has point to the benefits of modularity in the speed of
7 adoption (Wilson et al. 2020) and learning rates (Sweerts et al. 2020).

8 While many technologies do not fit into the solar model, some, including micro nuclear reactors and
9 direct air capture, also have modular characteristics that make them suitable for following solar's path
10 and benefit from solar's drivers. However, PV took solar 60 years to become cheap, which is too slow
11 for addressing climate change if a technology is now still at the lab scale. A challenge in learning from
12 the solar model is therefore to how to use public policy to speed up innovation over much shorter time
13 frames, e.g. 15 or less years.

14 **END BOX 16.4 HERE**

15

16 There are many definitions of policy mixes from various disciplines (Rogge et al. 2017), including
17 environmental economics (Lehmann 2012), policy studies (Kern and Howlett 2009) and innovation
18 studies. Generally speaking, a policy mix can be characterised by a combination of building blocks,
19 namely elements, processes and characteristics, which can be specified using different dimensions
20 (Rogge and Reichardt 2016). Elements include (i) the policy strategy with its objectives and principal
21 plans and (ii) the mix of policy instruments, and (iii) instrument design. The content of these elements
22 is the result of policy processes. Both elements and processes can be described by their characteristics
23 in terms of the consistency of the elements, the coherence of the processes, and the credibility and
24 comprehensiveness of the policy mix in different policy, governance, geography and temporal context
25 (Rogge and Reichardt 2016). Other aspects in the evaluation of policy mixes include framework
26 conditions, the type of policy instrument and the lower level of policy granularity, namely design
27 elements or design features (del Río 2014; del Río and Cerdá 2017). In addition, many have argued the
28 need to craft policies that affect different actors in the transition, some supporting and some
29 'destabilising' (see e.g. Kivimaa and Kern (2016) and Geels (2002)).

30 Learning from the innovation systems literature, some of the recent policy focus is not only directed on
31 innovation policies that can optimise the innovation system to improve economic competitiveness and
32 growth but also policies that can induce strategic directionality and guide processes of transformative
33 changes towards desired societal objectives (Mitcham 2003; Steneck 2006). Therefore, the aim is to
34 connect innovation policy with societal challenges and transformative changes through engagement
35 with a variety of actors and ideas and incorporating equity, nowadays often referred to as a just transition
36 (Newell and Mulvaney 2013; Swilling et al. 2016; Heffron and McCauley 2018; Jasanoff 2018) (see
37 Chapter 1 and Chapter 17). This new policy paradigm is opening up a new discursive space, shapes
38 policy outcomes, and is giving rise to the emerging idea of transformative innovation policy (Diercks
39 et al. 2019; Fagerberg 2018).

40 Transformative innovation policy has a broader coverage of the innovation process with a much wider
41 participation of actors, activities and modes of innovation. It is often expressed as socio-technical
42 transitions (Elzen et al. 2004; Turnheim and Sovacool 2020) or societal transformations (Scoones 2015;
43 Roberts et al. 2018). Transformative innovation policy encompasses different ideas and concepts that
44 aim to address the societal challenges involving a variety of discussions including social innovation
45 (Mulgan 2012), complex adaptive systems (Gunderson and Holling 2002), eco-innovation (Kemp 2011)
46 and framework for responsible innovation (Stilgoe et al. 2013), value-sensitive design (Friedman and
47 Hendry 2019) and social-technical integration (Fisher et al. 2006).

1 **16.4 Innovation policies and institutions**

2 Building on the frameworks for identifying market failures (Section 16.2) and systemic failures (Section
3 16.3) in the innovation system for climate-related technologies, Section 16.4 proceeds as follows. First,
4 it considers some of the policy instruments introduced in Chapter 13 that are particularly relevant for
5 the pace and direction of innovation in technologies for climate change mitigation and adaptation.
6 Second, it explains why governments put in place policies to promote innovation in climate related
7 technologies. Third, it takes stock of the overall empirical and theoretical evidence regarding the
8 relationship between policy instruments with a direct and an indirect impact on innovation outcomes
9 (including intellectual property regimes) and also other outcomes (competitiveness and distributional
10 outcomes). Fourth, it assesses the evidence on the impact of trade-related policies and of sub-national
11 policies aiming to develop cleantech industrial clusters.

12 This section focuses on innovation policies and institutions which are implemented at the national level.
13 Whenever relevant, this section highlights examples of policies or initiatives that delve more deeply
14 into the main high-level sectors: power, transport, industry, buildings, and AFOLU. Whenever possible,
15 this section also discusses issues in policy selection, design, and implementation that have been
16 identified as more relevant in developing countries and emerging economies.

17 Overall, this section shows that national and subnational policies and institutions are one of the main
18 factors determining the redirection and acceleration of technological innovation and low-emission
19 technological change (Åhman et al. 2017; Rogge and Reichardt 2016; Anadon et al. 2016b; Anadón et
20 al. 2017; Roberts et al. 2018) (*robust evidence, high agreement*). Both technology push (e.g., scientific
21 training, R&D) and demand pull (e.g., economic and fiscal support and regulatory policy instruments),
22 as well as instruments promoting knowledge flows and especially research-firm technology transfer,
23 can be part of the mix (*robust evidence, medium agreement*) (see also Sections 16.2 and 16.3).

24 Public R&D investments in energy and climate-related technologies have a positive impact on
25 innovation outcomes (*medium evidence, high agreement*). The evidence on procurement is generally
26 positive but limited. The record economic policy instruments that can be classified as market pull
27 instruments when it comes to the competitiveness outcome (at least in the short term) is more mixed.
28 The review of the literature in this section shows that market pull policy instruments had positive but
29 also some negative impacts on outcomes in some instances on some aspects of competitiveness and
30 distributional outcomes (*medium evidence, medium agreement*) (Peñasco et al. 2021). For several of
31 them, carbon taxes or feed-in tariffs for example, the evidence of a positive impact on innovation is
32 more consistent than the others. Evidence suggests that complementary policies or improved policy
33 design can mitigate such short-term negative distributional impacts.

34

35 **16.4.1 Overview of policy instruments for climate technology innovation**

36 Government policies can influence changes in technologies, as well as changes to the systems they
37 support (Somanathan et al. 2014) (see Chapter 13 and Sections 16.2 and 16.3).

38 Technology-push policy instruments stimulate innovation by increasing the supply of new knowledge
39 through funding and performing research; increasing the supply of trained scientists and engineers
40 which contribute to knowledge-generation and provide technological opportunities, which private firms
41 can decide to commercialise (Mowery and Rosenberg 1979; Anadon and Holdren 2009; Nemet 2009b;
42 Mazzucato 2013).

43 Governments can also stimulate technological change through demand-pull (or: market-pull)
44 instruments which support market creation or expansion and technology transfer and thus promoting
45 learning by doing, economies of scale, and automation (Section 16.2). Demand-pull policy instruments

1 include regulation, carbon prices, subsidies that reduce the cost of adoption, public procurement, and
 2 intellectual property regulation. Typically, technology push is especially important for early-stage
 3 technologies, characterised by higher uncertainty and lower appropriability (see Section 16.2); demand-
 4 pull instruments become more relevant in the later stages of the innovation process (Section 16.2)
 5 (Mowery and Rosenberg 1979; Anadon and Holdren 2009; Nemet 2009b).

6 The second column of Table 16.8 summarises the set of policies shaping broader climate outcomes over
 7 the past few decades in many countries outlined in Chapter 13 Section 13.6, which groups them into
 8 economic and financial, regulatory, and soft instruments. Other policies, such as monetary, banking and
 9 trade policies, for instance, can also shape innovation but most government action to shape energy has
 10 not focussed on them. As Table 16.8 shows, this section discusses the set of policy instruments on
 11 innovation outcomes, or a subset of the ‘Transformative Potential’ criterion presented in Chapter 13,
 12 and thus complements the more general discussion presented there. Table 16.8 specifically prioritizes
 13 the impact of the subset of policy instruments on innovation outcomes for which evidence is available.
 14 This focus is complemented by a discussion of the impact of the same policy instruments on
 15 competitiveness (a subcomponent of the economic effectiveness evaluation criterion) and on
 16 distributional outcomes. Many of the policy instrument types listed in Table 16.8 have been
 17 implemented or proposed to address different types of market or systemic failures or bottlenecks
 18 described in Section 16.2 and Section 16.3 (OECD 2011a).

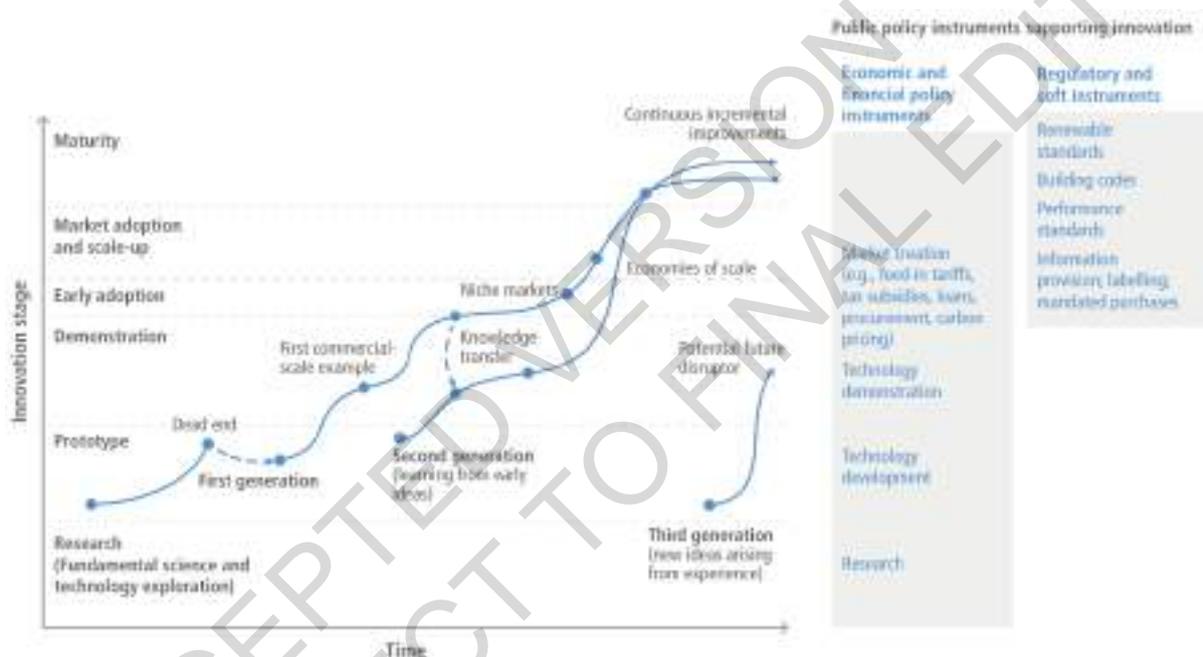

19
 20 **Table 16.8 Overview of policy instrument types covered in Chapter 13 and their correspondence to the**
 21 **subset of policy instrument types reviewed in Chapter 16 with a focus on innovation outcomes.**

High- level categorisation	Lower level policy instrument type in Chapter 13	Policy instrument types reviewed in Section 16.5 (for definitions see Peñasco et al (2021))
Economic or financial policy instrument types	R&D investments	R&D investments (including demonstration) (see Box 16.4 in Section 16.4)
	Subsidies for mitigation	Feed in tariffs or premia (set administratively)
		Energy auctions
		Other public financing options (public investment banks, loans, loan guarantees)
	Emissions trading schemes	Emissions trading scheme
	Carbon taxes	Taxes/tax relief (including carbon taxes, energy taxes and congestion taxes)
	Government provision	Government provision (focus on innovation procurement)
	Removing fossil fuel subsidies	<i>Not covered</i>
	Border carbon adjustments	<i>Not covered</i>
Offsets	<i>Not covered</i>	
Regulatory policy instrument types	Performance standards (including with tradeable credits)	Renewable obligations with tradeable green certificates
		Efficiency obligations with tradeable white certificates
		Clean energy or renewable portfolio standards (electricity)
		Building codes (building efficiency codes)
		Fuel efficiency standards
		Appliance efficiency standards

	Technology standards	<i>Not covered</i>
Soft policy instruments	Divestment and disclosure	<i>Not covered</i>
	Voluntary agreements (public voluntary programs & negotiated agreements)	Voluntary agreements Energy labels

1 Section 16.3 characterized technological innovation as a systemic, non-linear and dynamic process.
 2 Figure 16.1 below presents a stylized (and necessarily incomplete view) connecting the innovation
 3 process stages presented in Section 16.2, some of the key mechanisms in technology innovation
 4 systems, and some of the decarbonisation policy instruments that have been assessed in terms of their
 5 impact on technological innovation outcomes in Section 16.4.4. As noted in the caption and discussed
 6 in Section 16.4.4, regulatory policy instruments also shape the early stages of technology development.

7

8

9 **Figure 16.1 Technology innovation process and the (illustrative) and role of different public**
 10 **policy instruments (on the right-hand side). Adapted from IEA (IEA 2020a). Note that, as**
 11 **shown in section 16.4.4, demand pull instruments in the regulatory instrument category, for**
 12 **instance, can also shape the early stages of the innovation process. Their position on the latter**
 13 **stages is highlighted in this figure just because typically these instruments have been introduced**
 14 **in latter stages of the development of the technology.**

15

16 **16.4.2 The drivers and politics of national policies for climate change mitigation and** 17 **adaptation**

18 Governments around the world implement innovation policies in the energy and climate space with the
 19 aim of simultaneously advancing environmental, industrial policy (or competitiveness), and security
 20 goals (Surana and Anadon 2015; Meckling et al. 2017; Matsuo and Schmidt 2019; Anadón 2012;
 21 Peñasco et al. 2021) (*medium evidence, medium agreement*). Co-benefits of policies shaping
 22 technological innovation in climate-related technologies, including competitiveness, health, and
 23 improved distributional impacts can be drivers of climate mitigation policy in the innovation sphere

1 (Deng et al. 2018a; Stokes and Warshaw 2017; Probst et al. 2020). This was the case for climate and
2 air pollution policies with local content requirements for different types of renewable energy projects,
3 for instance, in places including China (Lewis 2014; Qiu and Anadon 2012), India (Behuria 2020),
4 South Africa (Kuntze and Moerenhout 2012), and Canada (Genest 2014) (*robust evidence, medium*
5 *agreement*).

6 The emergence of industries and support groups can lead to more sustained support for innovation
7 policies (Schmid et al. 2020; Stokes and Breetz 2018; Meckling 2019; Meckling and Nahm 2019;
8 Meckling et al. 2015a; Schmidt and Sewerin 2017a). Conversely, policies shaping technology
9 innovation contribute to the creation and evolution of different stakeholder groups (*robust evidence,*
10 *high agreement*). Most of the literature on the role of the politics and interest groups has focused on
11 renewable energy technologies although there is some work on heating in buildings (e.g. Wesche et al.
12 2019).

13 As novel technologies become cost-competitive, opposition of incumbents usually grows, as well as the
14 dangers of lock-in that can be posed by the new winner. Addressing this involves adapting policy
15 (*robust evidence, high agreement*).

16 Three phases of politics in the development of policies to meet climate and industrial objectives can be
17 identified, at the top, the middle and the bottom of the experience curve (Breetz et al. 2018) (see also
18 Figure 16.1 above, and Geels (2002)). In the first phase of ‘niche market diffusion’, the politics of more
19 sustained support for a technology or set of technologies become possible after a group of economic
20 winners and ‘clean energy constituencies’ are created (Meckling et al. 2015a). When technologies grow
21 out of the niche (second phase), they pose a more serious competition to incumbents who may become
22 more vocal opponents of additional support for innovation in the competing technologies (Stokes 2016;
23 Geels 2014a). In a third phase, path-dependence in policymaking and lock-in in institutions need to
24 change to accommodate new infrastructure, the integration of technologies, the emergence of
25 complementary technologies and of new regulatory regimes (Aklin and Urpelainen 2013; Levin et al.
26 2012).

27

28 **16.4.3 Indicators to assess the innovation, competitiveness and distributional outcomes** 29 **of policy instruments**

30 If policy instruments are created to (at least partly) shape innovation for systemic transitions to a zero-
31 carbon future, they also need to be evaluated on their impact on the whole socio-technical system (Neij
32 and Åstrand 2006) and a wide range of goals, including distributional impacts and competitiveness and
33 jobs (Stern 2007; Peñasco et al. 2021). Given this and the current policy focus on green recovery and
34 green industrial policy, although we primarily focus on innovation outcomes, we assess also impacts
35 on competitiveness and equity. Table 16.9 lists the selected set of indicators used to assess the impact
36 of the policy instrument types covered in right hand side column in Table 16.8. The table does not
37 include technology diffusion or deployment because these are covered in the technological effectiveness
38 evaluation criterion in Chapter 13. As noted in section 16.2, it is very difficult to measure or fully
39 understand innovation with one or even several indicators. In addition, all indicators have strengths and
40 weaknesses and may be more relevant in some countries and sectors than in others. The literature
41 assessing the impact of different policy instruments on innovation often covers just one of the various
42 indicators listed in the second column of Table 16.9.

43

44 **Table 16.9 Outcomes (first row) and indicators (second row) to evaluate the impact of policies shaping**
45 **innovation to foster carbon neutral economies.**

- 1 Sources: Innovation outcomes indicators are sourced from Del Rio and Cerdá (2014), and Peñasco et al (2021)
 2 Grubb et al (2021); the indicators under the competitiveness and distributional effects criteria are sourced from
 3 Peñasco et al (2021)

Policy Instrument Outcomes	Innovation (part of Chapter 13 'Transformative potential' evaluation criterion)	Competitiveness (part of Chapter 13 'Economic effectiveness' evaluation criterion)	Distributional impacts (defined in the same way as in Chapter13)
Examples of indicators used for each outcome in the literature	R&D investments, cost improvements, learning rates, patents, publications, reductions in abatement costs, energy efficiency improvements, other performance characteristics, firms reporting carbon saving innovation	Industry creation, net job creation, export of renewable energy technology equipment, economic growth (GNP, GDP), productivity, other investments	Level and incidence of support costs, change in spending on electricity as a % of total household spending, participation of different stakeholders, international equity (e.g., tCO ₂ -eq per capita), unequal access between large vs. small producers or firms

4

5 **16.4.4 Assessment of innovation and other impacts of innovation policy instruments**

6 While it is very difficult to attribute a causal relationship between a particular policy instrument
 7 implementation and different innovation indicators, given the complexity of the innovation system (see
 8 Section 16.3) there is a large quantitative and qualitative literature aiming to identify such impact.

9 **16.4.4.1 Assessment of the impact on innovation of technology push policy instruments: public** 10 **RD&D investments, other R&D incentives and public procurement**

11 Economic and direct investment policy instrument types are typically associated with a direct focus on
 12 technological innovation: R&D grants, R&D tax credits, prizes, national laboratories, technology
 13 incubators (including support for business development, plans), novel direct funding instruments (e.g.,
 14 ARPA-E), and innovation procurement.

15 Public RD&D investments have been found to have a positive impact on different innovation in energy
 16 and climate related technologies (*robust evidence, high agreement*), but the assessment relies almost
 17 entirely on evidence from industrialised countries. Out of 17 publications focussing on this assessment,
 18 only three found no relationship between R&D funding and innovation metrics (Peñasco et al. 2021;
 19 Goldstein et al. 2020; Doblinger et al. 2019). Sixteen out of them *used ex post* quantitative methods and
 20 one relied on theoretical *ex ante* assessment; only two of them included some non-industrialised
 21 countries, with one being the theoretical analysis. The evidence available does not point to public R&D
 22 funding for climate-related technologies crowding out private R&D (an important driver of innovation)
 23 but instead crowding it in. Box 16.6 summarizes the evidence available of the impact of ARPA-E (a
 24 public institution created in the United States in 2009 to allocate public R&D funding in energy) on
 25 innovation and competitiveness outcomes. Another institution supporting energy R&D that is the
 26 subject of much interest is the Fraunhofer Institute.

27 No evidence regarding the specific impact of R&D tax credits on climate mitigation or adaptation
 28 technologies has been found, but it is worth noting that generally speaking, R&D tax credits are found
 29 to incentivize innovation in firms in general, with an greater impact on small and medium firms (OECD
 30 2020). This is consistent with the fact that most of the evidence on the positive impact of public R&D
 31 support schemes covers small and medium firms (Howell 2017; Doblinger et al. 2019; Goldstein et al.
 32 2020). Although there is a high level of agreement in the literature regarding the impact of R&D

1 investments on innovation outcomes in climate-related technologies, it is important to note that this
2 evidence comes from industrialised countries. This does not mean that public R&D investments in
3 energy have been found to have no impact on developing countries innovation or competitiveness
4 outcomes, but rather that we were not able to find such studies focussing on developing countries.

5 Overall, public procurement has high potential to incentivise innovation in climate technologies, but
6 the evidence is mixed, particularly in developing countries (*limited evidence, medium agreement*).
7 Public procurement accounted for 13 % of gross domestic products in OECD in 2013 and much more
8 in some emerging and developing economies (Baron 2016). Its main goal is to acquire products or
9 services to improve public services, infrastructures and facilities and, in some cases, to also incentivize
10 innovation. It is important to implement several steps in the public procurement procedure to improve
11 transparency, minimise waste, fraud and corruption of public fund. These steps range from the
12 assessment of a need, issuance of a tender to the monitoring of delivery of the good or service. Box 16.5
13 outlines a public procurement program that was implemented in The Netherlands in 2005 with a focus
14 on green technologies. In spite of the fact that green procurement policies have been implemented, the
15 literature assessing the innovation impact of public procurement programs is relatively limited and
16 suggests either a positive impact or no impact (Peñasco et al. 2021; Alvarez and Rubio 2015; Fernández-
17 Sastre and Montalvo-Quizhpi 2019; Baron 2016). The majority of cases where the impact is positive
18 are analyses of industrialised countries, while no impact emerges in the case of a developing country
19 (Ecuador). More empirical research is needed to understand the impact of public procurement, which
20 has the potential to support the achievement of other societal challenges (Edler and Georgiou 2007;
21 Henderson and Newell 2011; ICLEI 2018; Baron 2016) in both developing and developed countries.

22 23 **START BOX 16.5 HERE**

24 **Box 16.5 Green Public Procurement in The Netherlands**

25 In 2005, the Dutch national government acknowledged a move in the House of Representatives to utilise
26 their annual spending power to promote the market for sustainable goods and services as well as to play
27 as a role model. Hence, a policy for environmentally friendly procurement was developed and
28 implemented across the national, local and provincial governments. Subsequently, sustainable public
29 procurement has expanded into a multidimensional policy in the Netherlands, accommodating policies
30 on green public procurement, bio-based public procurement, international social criteria, social return
31 on investment, innovation-oriented public procurement and circular economy.

32 The Green Public Procurement (GPP) policy is targeted at minimising the negative impacts of
33 production and consumption on the nature environment (Melissen and Reinders 2012; Cerutti et al.
34 2016). It includes a wide range of environmental criteria for different product groups that public
35 organisations frequently procure such as office equipment, uniforms, road works and catering. There
36 are 45 product groups (Melissen and Reinders, 2012) and 6 product clusters part of the government's
37 purchasing in terms of sustainability (PIANOo Expertisecentrum 2020). The six product clusters are: i)
38 Automation & telecommunications, ii) Energy, iii) Ground, road & hydraulic engineering, iv) Office
39 facilities and services, v) Office buildings, and vi) Transport (PIANOo Expertisecentrum 2020). The
40 GPP 2020 Tender Implementation Plan spells out the terms and conditions for making their green public
41 procurement. Some of these are confidential documents and are not shared online. Others are available
42 for download. The tender implementation plan for the Netherlands is available on
43 <https://gpp2020.eu/low-carbon-tenders/open-tenders/>. One of the important scenarios is that the public
44 procurers need the details of LCA analysis carried out in a tool called DuboCalc which calculates the
45 environmental impacts of the materials and methods of an infrastructural projects. GPP 2020 has
46 reported that three million tonnes of CO₂ would be saved in the Netherlands alone if all Dutch public
47 authorities applied the national Sustainable Public Procurement Criteria.

1 Research has been carried out to determine the prime mover for implementing Green Public
2 Procurement. An online survey of was administered among public procurement officers that subscribed
3 to the newsletters of two Dutch associations that provide advice and training to public procurers,
4 yielding a sample size of over 200 (Grandia and Voncken 2019). The first association is called NEVI
5 which is the only organisation in the Netherlands that offers certified procurement training programmes.
6 The second association is called PIANOo which is a public procurement expertise centre paid by the
7 Dutch national government for bringing together relevant information regarding public procurement
8 and providing public procurers with useful tools through their websites, workshops, meetings and
9 annual conferences. The data from the survey was then analysed using structural equations modelling
10 (SEM) and the results show that ability, motivation and opportunities affect the implementation of GPP.
11 Particularly, opportunity was found to affect green public procurement, innovation-oriented public
12 procurement and circular economy but not the other types of public procurement.

13 **END BOX 16.5 HERE**

15 **16.4.4.2 Assessment of the impact on competitiveness of technology push policy instruments: public** 16 **RD&D investments, other R&D incentives and public procurement**

17 Public R&D investments in the energy, renewables, environment space are generally associated with
18 positive impacts on industrial development or ‘competitiveness outcome’ (*robust evidence, medium*
19 *agreement*). In a number of cases negligible or negative impacts emerge (Peñasco et al. 2021; Goldstein
20 et al. 2020; Doblinger et al. 2019). The majority of these 15 analyses rely on *ex post* quantitative
21 methods, while only four use *ex ante* modelling approaches. Also, in this case, the vast majority of the
22 evidence is from industrialised countries.

23 There is limited and mixed evidence regarding the (positive or negative) impact of public procurement
24 for low-carbon or climate technologies and it emerges from developed countries (*limited evidence, low*
25 *agreement*). All of the four evaluations identified in the Peñasco et al (2021) review relied on qualitative
26 methods. One found a positive impact, another a negative impact and two others found no impact. All
27 of the studies covered European country experiences.

28 R&D and procurement policies have a positive impact on distributional outcomes (*limited evidence,*
29 *high agreement*). Peñasco et al (2021) identify three evaluations of the impact of RD&D funding on
30 distributional outcomes (two using quantitative methods and one *ex ante* theoretical methods) and one
31 of procurement on distributional outcomes (relying on qualitative analysis).

32 **16.4.4.3 Emerging insights on different public R&D and demonstration funding schemes**

33 The ability of a given R&D policy instrument to impact innovation and competitiveness depends to
34 some extent on policy design features (*limited evidence, high agreement*). As discussed in section
35 16.4.4.4, this is not unique to R&D funding. Most of these assessments use a limited number of
36 indicators (e.g., patents and publications and follow-on private financing, firm growth and survival,
37 respectively), focusses on the energy sector and on the US and other industrialised countries.
38 Extrapolating to emerging economies and low-income countries is difficult. There is no evidence on
39 the impact of different ways of allocating public energy R&D investments in the context of developing
40 countries.

41 Block funding, which tends to be more flexible, can lead to research that is more productive or novel,
42 but there are other factors that can affect the extent to which block funding can lead to more or less
43 novel outcomes (*limited evidence, medium agreement*). Research on national research laboratories,
44 which conduct at least 30% of all research in 68 countries around the world (Anadon et al. 2016a), are
45 a widespread mechanism to carry out public R&D and allocate funds, but assessments of their
46 performance is limited to developed countries. R&D priorities are also guided by institutions, and

1 research focussed on general technology innovation policy finds that institutions often do not embody
2 the goals of the poor or marginalized (Anadon et al. 2016b).

3 In the case of the US Department of Energy, block funding that can be quickly allocated to novel
4 projects (such as that allocated to National Labs as part of the Laboratory Directed Research and
5 Development—LDRD—funding) has been found to be associated with improved innovation indicators
6 (Anadon et al. 2016a). Research on Japan on R&D funding in general (not for climate-related
7 technologies) however, indicates that R&D funds allocated competitively result in higher novelty for
8 ‘high status’ (the term used in the paper to refer to senior male researchers), while block funding was
9 associated with research of higher novelty for lower status researchers (e.g., junior female researchers)
10 (Wang et al. 2018).

12 **START BOX 16.6 HERE**

13 **Box 16.6 ARPA-E a novel R&D funding allocation mechanism focussed on an energy mission**

14 One approach for allocating public R&D funds in energy involves relying on active program managers
15 and having clear technology development missions that focus on high-risk high-reward areas and
16 projects. This approach can be exemplified by a relatively new energy R&D funding agency in the US,
17 the Advanced Research Projects Agency for Energy (ARPA-E). This agency was created in 2009 and
18 it was modelled on the experience of DARPA (a US government agency funding high risk high reward
19 research in defence-related areas (Bonvillian and Van Atta 2011; Bonvillian 2018; U.S. National
20 Academies of Sciences Engineering and Medicine 2017). DARPA program managers had a lot of
21 discretion for making decisions about funding projects, but since energy R&D funding is usually more
22 politically vulnerable than defence R&D funding, the ARPA-E novel involved program managers
23 requesting external review as an informational input (Azoulay et al. 2019).

24 Like DARPA, ARPA-E program managers use an ‘active management approach that involves
25 empowering program managers to make decisions about funding allocation, milestones and goals.
26 ARPA-E managers also differ from other R&D allocation mechanisms in that ARPA-E staff retained
27 some control on the funded projects after the allocation of the funds. As argued by (Azoulay et al. 2019),
28 even though this relative control over the project can result in a reduction in the flexibility of funded
29 researchers, some ‘exploration’ happens at the program manager level.

30 Research on ARPA-E also sheds light on how program managers make decisions about what projects
31 to fund: about the process of project selection. Program managers do not just follow the rankings of
32 peer reviewers (sometimes projects with very disparate rankings were funded) and in many cases
33 program managers reported using information from review comments instead of the rankings (Goldstein
34 and Kearney 2020). Azoulay et al. (2019) suggest that if expert disagreement is a useful proxy for
35 uncertainty in research, then the use of individual discretion in ARPA-E would result in a portfolio of
36 projects with a higher level of uncertainty, as defined by disagreement among reviewers. Moreover,
37 under the premise that uncertainty is a corollary to novelty, individual discretion is an antidote to novelty
38 bias in peer review.

39 While innovation is notoriously hard to track and, particularly for emerging technologies, it can take a
40 lot of time to assess, early analysis has shown that this mission-orientation and more ‘actively managed’
41 R&D funding program may yield greater innovation patenting outcomes than other US energy R&D
42 funding programs and a greater or similar rate of academic publications when compared to other public
43 funding agencies in energy in the US, ranging from the Office of Science, the more applied Office of
44 Energy Efficiency and Renewable Energy or the small grants office (Goldstein and Narayanamurti
45 2018; U.S. National Academies of Sciences Engineering and Medicine 2017). In addition research
46 analysing the first cohort of cleantech start-ups has found that start-ups supported by ARPA-E had more

1 innovative outcomes when compared to those that had applied but not received funding, with others
2 that had not received any government support, and with others that had received other types of
3 government R&D support (Goldstein et al. 2020). Overall, the mission-oriented ARPA approach has
4 been successful in the United States when it comes to innovation outcomes. The extent to which it can
5 yield the same outcomes in other geographies with different innovation and financing environments
6 remains unknown. (*limited evidence, high agreement*).

7 **END BOX 16.6 HERE**

8
9 Public financing for R&D and research collaboration in the energy sector is important for small firms,
10 at least in industrialised countries, and it does not seem to crowd out private investment in R&D
11 (*medium evidence, high agreement*). Small US and UK firms accrue more patents and financing when
12 provided with cash incentives for R&D in the form of grants (Pless 2019; Howell 2017). US cleantech
13 start-ups which partner with government partners for joint technology development or licensing
14 partnerships accrue more patents and follow on financing (Doblinger et al. 2019).

15 Overall, the body of literature on public R&D funding design in energy and climate related technologies
16 provides some high-level guidance on how to make the most of these direct RD&D investments in
17 energy technologies in the climate change mitigation space, including: giving researchers and technical
18 experts autonomy and influence over funding decisions; incorporating technology transfer in research
19 organisations; focussing demonstration projects on learning; incentivising international collaboration
20 in energy research; adopting an adaptive learning strategy; and making funding stable and predictable
21 (Narayanamurti and Odumosu 2016; Narayanamurti et al. 2009; Chan et al. 2017) (*medium evidence,*
22 *high agreement*).

23 Without carefully designed public funding for demonstration efforts, often in a cost shared manner with
24 industry, the experimentation at larger scales needed for more novel technologies needed for climate
25 change mitigation may not take place. (*medium evidence, high agreement*). Government funding
26 specifically for technology demonstration projects, for RD&D (research, development and
27 demonstration) in energy technologies plays a crucial supporting role (Section 16.2.1). Governments
28 can facilitate knowledge spill-overs between firms, between countries, and between technologies (see
29 Section 16.2, Cohen et al (2002) and Baudry and Bonnet (2019)).

30 **16.4.4.4 Assessment of the impact on innovation and on competitiveness and distributional** 31 **outcomes of market pull policy instruments**

32 Demand pull policies such as tradeable green certificates, taxes, or auctions, are essential to support
33 scaling up efforts (Remer and Mattos 2003; Nahm and Steinfeld 2014; Wilson 2012). Just like for R&D
34 investments, research has indicated that effective demand pull needs to be credible, durable, and aligned
35 with other policies (Nemet et al. 2017) and that the effectiveness of different demand pull instruments
36 depends on policy design (del Río and Kiefer 2021). Historical analyses of the relative importance of
37 demand pull and technology push are clear; both are needed to provide robust incentives for investment
38 in innovation. Interactions between them are central as their combination enables innovators to connect
39 a technical opportunity with a market opportunity (Grubler and Wilson 2013; Freeman 1995b;
40 Jacobsson et al. 2004). It is important to note that these market pull policies are often put in place
41 primarily to meet security and/or environmental goals, although innovation and competitiveness are
42 sometimes also pursued explicitly.

43 *Emission Trading Schemes*

44 Overall evidence suggests that the emissions trading schemes, as currently designed, have not
45 significantly contributed to innovation outcomes (*medium evidence, medium/high agreement*).

1 Penasco et al. (2021) review 20 evaluations: eight identified a positive impact (although in at least two
2 cases the paper indicated the impact was small or negligible), 11 no impact and one was associated with
3 a negative impact on innovation indicators. The studies that found no impact and the studies that found
4 some impact covered all three methods covered (quantitative *ex post*, qualitative and theoretical and *ex*
5 *ante* analysis). Another review focussed only on empirical studies (mainly quantitative but also
6 qualitative), covered a slightly longer period and identified 19 studies (15 using quantitative methods)
7 (Lilliestam et al. 2021). With a narrower set of indicators of innovation, they concluded there was very
8 little empirical evidence linking the emissions trading schemes studied to date and innovation
9 (Lilliestam et al. 2021). This review focussed mainly on papers evaluating the earlier stages of the
10 European Emissions Trading Scheme, which featured relatively low CO₂ prices and covered a small set
11 of firms, showing that carbon pricing policy design is an important determinant of innovation outcomes.
12 Combining both reviews, there are a total of 27 individual studies, some of them providing mixed
13 evidence of impact, and 23 of them suggest there was no impact or (in a couple of cases) it was small.
14 It is important to note that some researchers note that, for particular subsectors and actors, emissions
15 trading schemes have had an impact on patenting trends (Calel and Dechezleprêtre 2016). Overall the
16 expectation is that higher prices and coverage would result in higher impacts and that, over time, the
17 impact on innovation would grow.

18 *Carbon and environmental taxes*

19 The impact of carbon taxes on innovation outcomes is more positive than that for ETS schemes but the
20 evidence is more limited (*limited evidence, medium agreement*). Assessments of their impact on
21 innovation metrics have been very limited, with only four studies (three quantitative and one *ex ante*).
22 Three of the studies found a positive impact of carbon taxes on innovation outcomes and one found no
23 impact (Peñasco et al. 2021).

24 Depending on the design (including the value and coverage of the tax), carbon taxes can either have
25 positive, negative or null impact on competitiveness and distributional outcomes (*medium evidence,*
26 *medium agreement*). The evidence on the impact of carbon taxes on competitiveness is significant (a
27 total of 27 evaluations) and mixed, with six of them reporting some positive impacts, ten reporting no
28 impact, and 11 reporting negative impacts (so 59% were not associated with negative impacts). Most
29 of the evaluations reporting negative impacts were theoretical assessments, and only three *ex post*
30 quantitative analysis (Peñasco et al. 2021). 24 evaluations covered distributional impacts of carbon
31 taxes and other environmental taxes and the majority (15) found the existence of some negative
32 distributional impacts, six found positive impacts and three no distributional impacts. Differences in the
33 result of the assessments stem from the design of the taxes (Peñasco et al. 2021). It is important to note
34 that, once again, the evidence comes from industrialized countries and emerging economies.

35 *Feed-in-Tariffs*

36 Many factors affect the impacts of feed in tariffs on outcomes other than innovation (*robust evidence,*
37 *high agreement*). While FITs have been generally associated with positive innovation outcomes, some
38 of the differences found in the literature may arise from differences in the evaluation method (Peñasco
39 et al. 2021) or differences in policy design (e.g., the level and the rate of decrease of the tariff)
40 (Hoppmann et al. 2014), the policy mixes (Rogge et al. 2017), the technologies targeted and their stage
41 of development (Huenteler et al. 2016b), and the geographical and temporal context of where the policy
42 was put in place (Section 16.3). Research has also found that, particularly for less mature technologies,
43 a higher technology specificity in the design of FITs is associated with more innovation (Del Río 2012).
44 Feed-in-tariffs yield better results if they account for the specificities of the country; else, the technology
45 and the policy could result in negative distributional and (to a lesser extent) competitiveness impacts.
46 Meckling et al (2017) indicate that an ‘enduring challenge’ of technology-specific industrial policy such
47 as some feed-in-tariffs is to avoid locking in suboptimal clean technologies—a challenge which, among
48 other options, could be overcome with targeted niche procurement for next generation technologies.

1 Other authors have cautioned that the move from renewable feed-in-tariffs to auctions may favour
2 existing PV (e.g., polysilicon) over more novel solar power technologies (Sivaram 2018b) such as thin-
3 film PV, amorphous PV, and perovskites.

4 Policy design, policy mixes, and domestic capacity and infrastructure are important factors determining
5 the extent to which economic policy instruments in industrialised countries and emerging economies
6 can also lead to positive (or at least not negative) competitiveness outcomes and distributional outcomes
7 (*medium evidence, medium agreement*) (Section 16.3). Prioritising low cost energy generation in the
8 design of FIT schemes can result in a lower focus of innovation efforts on more novel technologies and
9 greater barriers to incumbents in less mature technologies (Hoppmann et al. 2013). Similarly, case study
10 research from Mexico and South Africa indicates that focusing on low-cost renewable energy
11 generation only can result in a greater reliance on existing foreign value chains and capital, and thus in
12 lower or negative impacts on domestic competitiveness—in other words, some approaches can hinder
13 the development of the local capabilities that could result in greater long-term benefits domestically
14 (Matsuo and Schmidt 2019). Evidence for developing countries indicates that local and absorptive
15 capacity also play an important role in particular on the ability of policies to contribute to
16 competitiveness or industrial policy goals (e.g., Binz and Anadon 2018). Research comparing China’s
17 and India’s policies and outcomes on wind also suggest that policy durability and systemic approaches
18 can affect industrial outcomes (Surana and Anadon 2015).

19 *Energy auctions*

20 The evidence of the impact of renewable energy auctions on innovation outcomes is very small and
21 provides mixed results (*limited evidence, low agreement*). Out of six evaluations, three of them identify
22 positive impacts, two no impacts, and one negative impacts. All of the evaluations but one were
23 qualitative or theoretical and the quantitative assessment indicated no impact (Peñasco et al. 2021).
24 There is more evidence covering emerging economies analysing the impacts of auctions when
25 compared to other policy instrument types. For example, there is work comparing the approaches to
26 renewable energy auctions in South Africa and Denmark (Toke 2015) finding a positive impact on the
27 latter stages of innovation (mainly deployment), and broader work on auctions covering OECD
28 countries as well as Brazil, South Africa and China not finding a significant impact on innovation
29 (Wigand et al. 2016), and work comparing renewable energy auctions in different countries in South
30 America finding generally a positive impact on innovation outcomes (Mastropietro et al. 2014). The
31 body of evidence on the impact of auctions on competitiveness is also limited (six evaluations) and
32 indicates negative outcomes of renewable auctions of competitiveness (*limited evidence, low*
33 *agreement*). As with other policies, the design of the auctions can affect innovation outcomes (del Río
34 and Kiefer 2021). Only two studies investigated distributional outcomes and both were negative.

35 *Other financial instruments*

36 There is no explicit literature on the ability of green public banks, and targeted loans, and loan
37 guarantees to lead to upstream innovation investments and activities, although there is evidence on their
38 role in deployment (see e.g. Geddes et al (2018)). This notwithstanding the key role of these institutions
39 in the innovation system (Sections 16.2.1 and 16.3) (OECD 2015c; Geddes et al. 2018) and the belief
40 that they can de-risk scale-up and the testing of business models (Probst et al. 2021; Geddes et al. 2018)
41 (see Chapter 17).

42 *Renewable obligations with tradeable green certificates*

43
44 There is mixed evidence of the impact of tradeable green certificates (TGCs) on innovation (*limited*
45 *evidence, low agreement*) and competitiveness (*limited evidence, low agreement*). Out of the 11
46 evaluations in Peñasco et al (2021), six found no impact, two a positive impact, and three a negative
47 impact. All of them used a qualitative research approach. Of the six studies focusing on competitiveness
48 outcomes, three conclude TGCs have had no impact on competitiveness, while two indicate negative
49

1 impact and one a positive impact. Only one of the studies was quantitative and did not identify an impact
2 on competitiveness.

3 TGC are associated with the existence of negative distributional impacts in most applications (*medium*
4 *evidence, high agreement*). Ten out of 12 studies identify the existence of some negative impacts. All
5 but one of these studies (which focussed on India) are based on analysis of policies implemented in
6 industrialised countries.

7 *Clean Energy and renewable Portfolio Standards*

8 The impact of renewable portfolio standards without tradeable credits on innovation outcomes is
9 negligible or very small (*medium evidence, medium agreement*). Out of the nine studies, seven reported
10 no impact on innovation outcomes and two a positive impact (Peñasco et al. 2021). Most of these papers
11 focussed on patenting and private R&D innovation indicators and not cost reductions. Impact on
12 competitiveness is found to be negligible or positive (*limited evidence, medium agreement*). Out of
13 eight evaluations, five report positive impact and three negligible impact; only two are quantitative
14 studies (Peñasco et al. 2021). Negative distributional impacts from renewable portfolio standards can
15 emerge in some cases (*limited evidence, low agreement*). Out of eight evaluations, four identified
16 positive impacts, and four negative impacts; all of the studies identifying a positive impact were
17 theoretical. There are efforts focussed on clean energy portfolio standards which include technologies
18 beyond renewables.

19

20 *Efficiency obligations with tradeable credits*

21 The impact of tradeable white certificates in innovation is largely positive, but the evidence is limited
22 (*limited evidence, medium/high agreement*). Out of four evaluations, only one of which was
23 quantitative, three report positive impact and one no impact (Peñasco et al. 2021). The impact of white
24 certificates on competitiveness is positive (*limited evidence, high agreement*) while that on
25 distributional outcomes is very mixed (*limited evidence, low agreement*). Two theoretical studies report
26 positive competitiveness impacts. Out of 11 evaluations of distributional outcomes, eight rely on
27 theoretical *ex ante* approaches. Seven evaluations reported positive impacts (four of them using
28 theoretical methods), three of them (using theoretical methods) indicated negative impacts and one of
29 them no impact.

30

31 *Building codes*

32 There is evidence of the impact of building codes on innovation outcomes (Peñasco et al. 2021). Only
33 two studies assessed competitiveness impacts (one identifying positive impacts and one negligible ones)
34 and three studies identifying distributional impacts, all positive.

35 Overall, the evidence on the impact of the market pull policy instruments covered in Section 16.4.4.4
36 when it comes to the competitiveness outcome (at least in the short term) is more mixed. For some of
37 them, the evidence of a positive impact on innovation is more consistent than the others (for carbon
38 taxes or FITs, for example). Peñasco et al (2021) found that the disagreements in the evidence regarding
39 the positive, negative or no impact of a policy on competitiveness or distributional outcomes can often
40 be explained by differences in policy design, differences in geographical or temporal context (since the
41 review included evidence from countries from all over the world), or on how policy mixes may have
42 affected the ability of the research design of the underlying papers to separate the impact of the policy
43 under consideration from the others.

44

45 **16.4.4.5 Assessment of the impact on innovation, competitiveness and distributional outcomes of** 46 **regulatory policy instruments targeting efficiency improvements**

47 There is medium evidence that the introduction of flexible, performance-based environmental
48 regulation on energy efficiency in general (e.g., efficiency standards) can stimulate innovative

1 responses in firms (Ambec et al. 2013; Popp 2019) (*medium evidence, high agreement*). Evidence
2 comes from both observational studies that examine patenting, R&D or technological responses to
3 regulatory interventions, and from surveys and qualitative case studies in which firms report regulatory
4 compliance as a driving force for the introduction of environmentally-beneficial innovations (Grubb et
5 al. 2021). While the literature examining the impact of environmental regulation on innovation is large,
6 there have been fewer studies on the innovation effects of minimum energy or emissions performance
7 regulations specifically relating to climate mitigation. We discuss in turn two types of efficiency
8 regulations: on vehicles, and on appliances.

9 *Relationship between automotive efficiency regulations and innovation*

10 The announcement, introduction and tightening of vehicle fleet efficiency or GHG emission standards
11 either at the national or sub-national level positively impacts innovation as measured by patents
12 (Barbieri 2015) or vehicle characteristics (Knittel 2011; Kiso 2019) as summarised in a review by
13 Grubb et al (2021). Detailed studies on the innovation effects of national pollutant (rather than energy)
14 regulations on automotive innovation also indicate that introducing or tightening performance standards
15 has driven technological change (Lee et al. 2010). Some studies in the US that examine periods in which
16 little regulatory change took place have found that the effects of performance standards on fuel economy
17 have been small (Knittel 2011) or not significant relative to the innovation effects of prices (Crabb and
18 Johnson 2010). This is at least in part because ongoing efficiency improvements during this period were
19 offset by increases in other product attributes. For example, Knittel (2011) study observed that size and
20 power increased without a corresponding increase in fuel consumption. It has also been observed that
21 regulatory design may introduce distortions that affect automotive innovation choices: in particular,
22 fuel economy standards based on weight classes have been observed to distort light-weighting strategies
23 for fuel efficiency in both China (Hao et al. 2016) and Japan (Ito and Sallee 2018).

24 A number of studies have focused on the impacts of a sub-national technology-forcing policy: the
25 California Zero Emission Vehicle (ZEV) mandate. When it was introduced in 1990, this policy required
26 automotive firms to ensure that 2% of the vehicles they sold in 1998 would be zero emissions. In the
27 years immediately after introduction of the policy, automotive firms reported that it was a significant
28 stimulus to their R&D activity in electric vehicles (Brown et al. 1995). Quantitative evidence examining
29 patents and prototypes has indicated that the stringency of the policy was a significant factor in
30 stimulating innovation, though this was in part dependent on firm strategy (Sierzchula and Nemet 2015).
31 Like in the previous instruments, most of the evidence comes from industrialised countries and
32 additional research on other countries would be beneficial.

33 *Relationship between appliance efficiency standards and innovation*

34 Regulation-driven deployment of existing technologies can generate innovation in those technologies,
35 through learning-by-doing, induced R&D and other mechanisms, although not in all cases (Grubb et al.
36 2021) (*medium evidence, medium agreement*). The introduction or tightening of minimum energy
37 performance standards for appliances (and in the case of Noailly (2012) for buildings) have driven
38 innovation responses, using direct measures of product attributes (Newell et al. 1999) and patents
39 (Noailly 2012; Kim and Brown 2019), though not all studies have found a significant relationship
40 (Girod et al. 2017). There is also evidence of a correlation between regulation-driven deployment of
41 energy-efficient products with accelerated learning in those technologies (Van Buskirk et al. 2014; Wei
42 et al. 2017).

43 In addition to observational studies, evidence on the relationship between innovation and regulation
44 comes from surveys in which survey respondents are asked whether they have engaged in innovation
45 leading to energy saving or reduced GHG emissions, and what the motivations were for such innovation.
46 Survey evidence has found that expected or current regulation can drive both R&D investment and
47 decisions to adopt or introduce innovations that reduce energy consumption or CO₂ emissions (Horbach
48 et al. 2012; Grubb et al. 2021). Survey-based studies, however, tend not to specify the type of regulation.

1 *Competitiveness and distributional impacts associated with vehicles and appliance performance*
2 *standards*

3 Minimum energy performance standards and appliance standards have been known to result in negative
4 distributional impacts (*limited evidence, medium/high agreement*). Several studies focused on the US
5 have highlighted that minimum energy performance standards for vehicles tend to be regressive, with
6 poorer households disproportionately affected (Levinson 2019; Jacobsen 2013), particularly when
7 second-hand vehicles are taken into account (Davis and Knittel 2019). Similar arguments, though with
8 less evidence, have been made for appliance standards (Sutherland 2006).

9 Overall, the extent to which regulations in energy efficiency result in positive or negative
10 competitiveness impacts in firms is mixed (*limited evidence, high disagreement*). A meta-analysis of
11 107 studies, of which 13 focused on regulations relating to energy consumption or GHG emissions,
12 found that around half showed that regulations resulted in competitiveness impacts, while half did not
13 (Cohen and Tubb 2018). Cohen and Tubb (2018) also found that studies examining performance-based
14 regulations were less likely to find positive competitiveness impacts than those that examined market-
15 based instruments.

16 *Insights into causal mechanisms and co-evolutionary dynamics from case studies on efficiency*
17 *regulations*

18 While most of the literature addresses the extent to which regulation can induce innovation, a number
19 of case studies highlight that innovation can also influence regulation, as the costs of imposing
20 regulation are reduced and political interests emerge that seek to exploit competitive advantages
21 conferred by successfully developing energy-efficient or low-carbon technologies (*medium evidence,*
22 *high agreement*). Case studies map the causal mechanisms relating regulations and innovation
23 responses in specific firms or industries (Ruby 2015; Wesseling et al. 2015; Kemp 2005; Gann et al.
24 1998).

25
26 **16.4.4.6 Assessment of the impact on innovation and on competitiveness and distributional**
27 **outcomes of soft instruments**

28 *Energy labels and innovation*

29 The literature specifically focusing on the impacts of labels is very limited and indicates positive
30 outcomes (*limited evidence, high agreement*). Energy labels may accompany a minimum energy
31 performance standard and the outcomes of these policies are often combined in literature (IEA 2015).
32 But again, given the limited evidence more research is needed. Although there are many studies on
33 energy efficiency more broadly and for both standards and labels, only eight studies specifically focus
34 on labels. Furthermore, seven of them report positive outcomes and one negative outcomes. Six of the
35 studies used qualitative methods mentioning the impacts of labelling on the development of new
36 products (Wiel et al. 2006). Research specifically comparing voluntary labels with other mechanisms
37 found a significant and positive relationship between labels and the number of energy-efficient
38 inventions (Girod et al. 2017). More research is needed especially in developing countries that have
39 extensive labelling programs in place, and also with quantitative methods, to develop evidence on the
40 impacts of labelling on innovation. Box 16.7 discusses an example of a combination of policy
41 instruments in China including labelling, bans and financial support.

42

43 **START BOX 16.7 HERE**

44 **Box 16.7 China Energy Labelling Policies, combined with sale bans and financial subsidies**

45 From 1970 to 2001, China was able to significantly limit energy demand growth through energy-
46 efficiency programs. Energy use per unit of gross domestic product (GDP) declined by approximately
47 5% yr⁻¹ during this period. However, between 2002 and 2005, energy demand per unit of GDP increased

1 on average by 3.8% yr⁻¹. To curb this energy growth, in 2005, the Chinese government announced a
2 mandatory goal of 20% reduction of energy intensity between 2006 and 2010 (Zhou et al. 2010; Lo
3 2014).

4 An Energy Labelling System was passed in 2004. It requires the manufacturers to provide information
5 about the efficiency of their electrical appliances to consumers. From 2004 to 2010, 23 electrical
6 appliances (including refrigerators, air conditioners and flat-screen TVs) being labelled as energy
7 efficient with 5 different grades, with Grade 1 being the most energy efficient and grade 5 the least
8 efficient. Any appliances with an efficiency grade higher than 5 cannot be sold in the market.

9 In addition to providing information to consumers, the National Development Reform Commission,
10 which was in charge of designing the policies, and the Ministry of Finance launched in 2009 the
11 “energy-saving products and civilian-benefiting project” (Zhan et al. 2011). It covered air conditioners,
12 refrigerators, flat panel televisions, washing machines, electrical efficient lighting, energy saving and
13 new energy vehicles with the energy grades at 1 or 2 and it consisted of financial subsidies for
14 enterprises producing these products. The standard design of these financial subsidies involved the
15 government paying for the price difference of energy efficiency products and general products. The
16 manufacturers which produce the energy efficient products can get the financial subsidies directly from
17 the government (Wang et al. 2017b).

18 Before 2008, the market share of grade 1 and grade 2 air conditioners was about 5%, and about 70% of
19 all air conditioners were grade 5 (the most inefficient). Driven by the financial subsidies, the selling
20 price of the highly efficient air conditioners became competitive with that of the general air
21 conditioners. Hence, the sales of energy efficient air conditioners increased substantially, making the
22 market share of air conditioners at grade 1 and 2 to be about 80% in 2010 (Wang et al. 2017b).
23 According to the information from energy efficiency labelling management centre of China National
24 Institute of Standardisation, under the energy label system implemented 5 years ago, more than 1.5
25 hundred billion kWh power was saved by March 2010, equivalent to more than 60 million tons of
26 standard coal, 1.4 billion tons of carbon dioxide emissions, and 60 tons of sulphur dioxide emissions
27 (Zhan et al. 2011), which significantly contributed to energy saving goals of the 11th Five-Year Plan.

28 **END BOX 16.7 HERE**

29 *Voluntary approaches and innovation*

30 Voluntary approaches have a largely positive impact on innovation for those that choose to participate
31 (*robust evidence, medium agreement*). Research on voluntary approaches focuses on firms adopting
32 voluntary environmental management systems that can be certified based on standards of the widely
33 adopted International Standards Organisation (ISO 14001) or the European Union Environmental
34 Management and Auditing Scheme (EMAS), which is partly mandatory today. Out of 16 analyses, 70%
35 report positive innovation outcomes in terms of patents, or product and process innovation. 17% report
36 negligible impacts and 13% report negative impact. Positive innovation outcomes have been linked to
37 firms’ internal resource management practices and were found to be strengthened in firms with mature
38 environmental management systems and in the presence of other environmental regulations (He and
39 Shen 2019; Inoue et al. 2013; Li et al. 2019a). Overall, studies are concentrated in a few countries that
40 do not fully capture where environmental management systems have been actually adopted (Boiral et
41 al. 2018). There is a need for research in analyses of such instruments in emerging economies including
42 China and India, and methodologically in qualitative and longitudinal analyses (Boiral et al. 2018).

43 *Competitiveness and distributional outcomes of soft instruments*

44 The outcomes for performance or endorsement labels have been associated with positive
45 competitiveness outcomes (*medium evidence, medium agreement*). Out of 19 studies, 89% report
46 positive impact and 11% negligible impact. Although there are several studies analysing
47 competitiveness related metrics, evidence on most individual metrics is sporadic, except for housing

1 premiums. A large number of studies quantitatively assessing competitiveness find that green labels in
2 buildings are associated with housing price premium in multiple countries and regions (Fuerst and
3 McAllister 2011; Kahn and Kok 2014; Zhang et al. 2017). 32% of the studies were qualitative,
4 associating appliance labelling programs with employment and industry development (European
5 Commission 2018). There is a research gap in analyses of developing countries, and also in
6 quantitatively assessing outcomes beyond housing price premiums.

7 A few studies on the distributional outcomes of voluntary labelling programs point to positive impacts
8 (*limited evidence, high agreement*). All four studies focusing benefits for consumers and tenants, report
9 positive impacts (Devine and Kok 2015). Although there are benefits for utilities and other stakeholders,
10 more research is needed specifically attribute these benefits to voluntary labels rather than energy
11 efficiency programs in general.

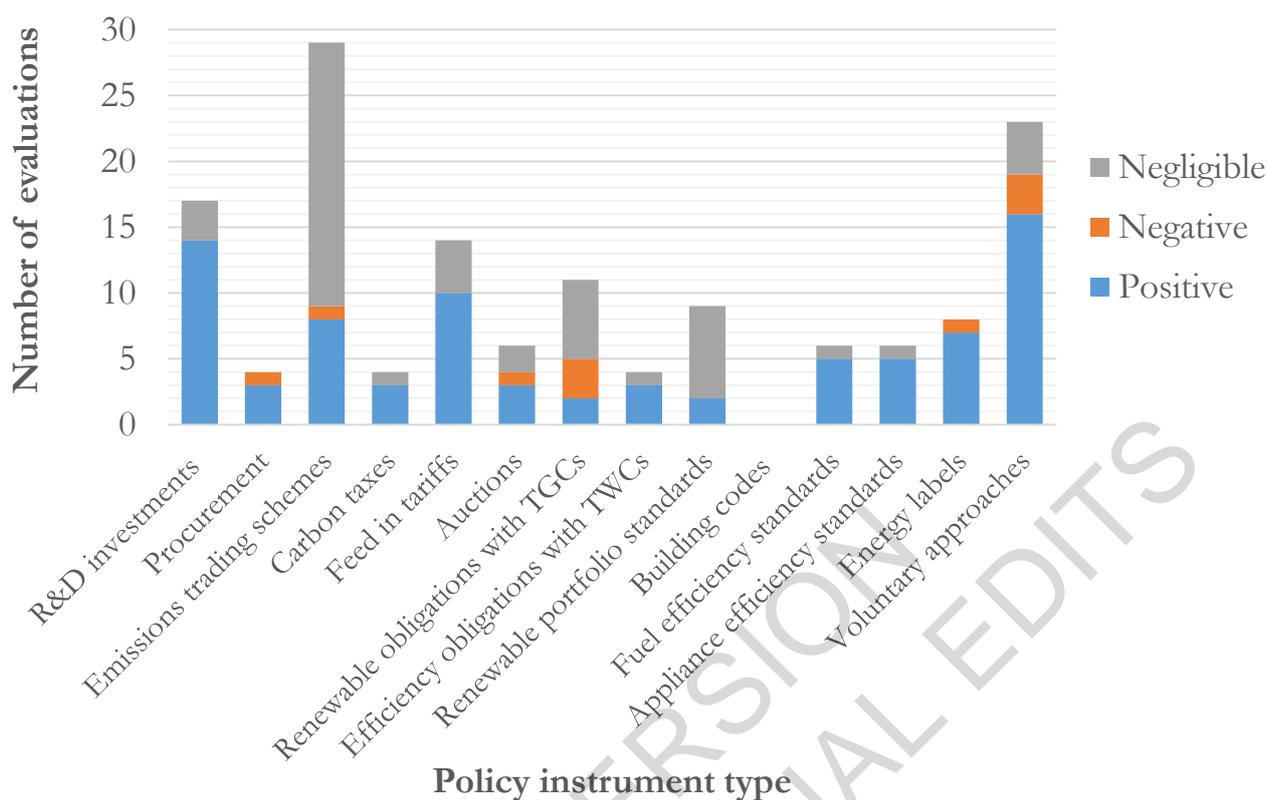

12 Voluntary agreements are associated with positive competitiveness outcomes (*medium evidence,*
13 *medium agreement*), 14 out of 19 evaluations identified were associated with positive outcomes while
14 three were associated with negligible outcomes, and two with negative outcomes. Research found an
15 increase in perceived firm financial performance (de Jong et al. 2014; Moon et al. 2014). Studies also
16 show an association with higher exports as more environmentally conscious trade partners increasingly
17 value environmental certifications (Belleli et al. 2005). More research is needed to develop evidence
18 on metrics of competitiveness besides firms' financial performance, and especially in developing
19 countries.

20 Voluntary agreements are associated with a positive impact on distributional outcomes (*limited*
21 *evidence, high agreement*). Five studies, mainly using qualitative approaches, report a positive
22 association between a firm adopting an environmental management system and impacts on its supply
23 chains. There is a need for more studies with quantitative assessments and geographical diversity.

25 ***16.4.4.7 Summary of the size and direction of the evidence of all policy instrument types on*** 26 ***innovation outcomes***

27 Positive impacts have been identified more frequently in some policies than in others. There is also a
28 lot of variation in the density of the literature. Developing countries are severely underrepresented in
29 the decarbonisation policy instrument evaluation literature aiming to understand the impact on
30 innovation. (*high evidence, high agreement*).

31 Figure 16.2 below indicates the extent to which some decarbonisation policy instruments have been
32 more or less investigated in terms of their impact on innovation outcomes as described in Table 16.9
33 above. For example, it indicates the extent to which there has been a greater focus of evaluations of the
34 impact of R&D investments, emissions trading schemes and voluntary approaches on innovation. It
35 also shows a limited amount of evidence on procurement, efficiency obligations with tradeable green
36 certificates (TGCs), building codes and auctions.

1

2 **Figure 16.2** Number of evaluations available for each policy instrument type covered regarding their
3 impact on innovation and direction of the assessment. The vertical axis displays the number of
4 evaluations claiming to isolate the impact of each policy instrument type on innovation outcomes as listed
5 in Table 16.9. The colour indicates whether each evaluation identified a positive impact on the innovation
6 outcome (blue), the existence of a negative impact (in orange), and no impact (in grey). It builds on
7 Peñasco et al (2021), Grubb et al (2021), Lilliestam et al (2021) and additional studies identified as part of
8 these reviews. TGC stands for tradeable green certificates. TWC stands for tradeable white certificates.

9

10 **16.4.5 Trade instruments and their impact on innovation**

11 There has been a long interest on the impact of Foreign Direct Investment (FDI) on domestic capacity
12 on innovation and on environmental outcomes. This section does not cover the much larger body of
13 evidence on the relationship between FDI and economic development and growth.

14 Overall, research indicates that trade can facilitate the entrance of new technologies, but the impact on
15 innovation is less clear (*limited evidence, low agreement*). A recent study indicates that for countries
16 with high environmental performance FDI has a negligible impact on environmental performance,
17 while on the lower end of the spectrum (countries with a lower environmental performance) may benefit
18 from FDI in terms of their environmental performance (Li et al. 2019b). One analysis on China links
19 FDI not just with improved environmental performance and energy efficiency but also innovation
20 outcomes in general (Gao and Zhang 2013). Other work links FDI with increased productivity across
21 firms (not just those engaged in climate-related technologies) through spill-overs (Newman et al. 2015).
22 In addition, Brandão and Ehrl (2019) indicate that productivity of the electric power industry is more
23 influenced by the transfer of embodied technology from other industries than by investments of the
24 power industry and that countries with high R&D stocks are the main sources of these international
25 technology spillovers and that the source countries may also benefit from the spillover.

1 Other emerging work investigates the role of local content requirements on innovation outcomes and
2 suggests that it can lead to increased power costs (negative distributional impacts) and the domestic
3 innovation system benefits, measured by patents or exports are unclear if the policies are not part of a
4 holistic and longer lasting policy framework (Probst et al. 2020).

6 **16.4.6 Intellectual property rights, legal framework and the impact on innovation**

7 Virtually all countries around the world have instituted systems for the protection of creations and
8 inventions, known as Intellectual Property (IP) rights systems (WIPO 2021). While several types of
9 intellectual property exist – patents, copyright, design rights, trademarks, and more –, this section will
10 focus on patents, as the most relevant property right for technological innovations (World Intellectual
11 Property Organization 2008), and hence the most relevant for policy instruments in this context.

12 Patent systems aim to promote innovation and economic growth, by stimulating both the creation of
13 new knowledge and diffusion of that knowledge (*high evidence, high agreement*). National patent
14 systems, as institutions, play a central role in theories on national innovation systems (*high evidence,*
15 *strong agreement*). Patent systems are usually instituted to promote innovation and economic growth
16 (Nelson and Mazzoleni 1996; Machlup and Penrose 1950; Encaoua et al. 2006). Some countries
17 explicitly refer to this purpose in their law or legislation – for instance, the US Constitution states the
18 purpose of the US IP rights system to “promote the progress of science and useful arts”. Patent systems
19 aim to reach their goals by trying to strike a balance between the creation of new knowledge and
20 diffusion of that knowledge (Scotchmer and Green 1990; Devlin 2010; Anadon et al. 2016b). They
21 promote the creation of new knowledge (e.g. technological inventions) by providing a temporary,
22 exclusive right to the holder of the patent, thus providing incentives to develop such new knowledge
23 and helping parties to justify investments in research and development. They promote the diffusion of
24 this new knowledge via the detailed disclosure of the invention in the patent publication, and by
25 enabling a ‘market for knowledge’ via the trading of patents and the issuance of licenses (Arora et al.
26 2004). Although IP protections provide incentives to invest in innovation, they have the double effect
27 of restricting the use of new knowledge by raising prices or blocking follow-on innovation (Stiglitz
28 2008; Wallerstein et al. 1993). National patent systems, as institutions, feature prominently in models
29 and theories of National Innovation Systems (Edquist 1997; Klein Woolthuis et al. 2005).

30 The degree to which patent systems actually promote innovation is subject to debate. Patent protection
31 has been found to have a positive impact on R&D activities in patent-intensive industries, but this effect
32 was found to be conditional on access to finance (Maskus et al. 2019). Patents are believed to be
33 especially important to facilitate innovation in selected areas like pharmaceuticals, where investments
34 in developments and clinical trials are high, imitation costs are low, and there is often a 1:1 relationship
35 between a patent and a product, referred to as a “discrete” product industry (Cohen et al. 2000). At the
36 same time, there is an increasing body of theoretical and empirical literature that suggests that the
37 proliferation of patents also discourages innovation (*medium evidence, low agreement*). Theoretical
38 contributions note that a too stringent appropriability regime may greatly limit the diffusion of advanced
39 technological knowledge and eventually block the development of differentiated technological
40 capabilities within an industry, in what is called an ‘appropriability trap’ (Edquist 1997; Klein
41 Woolthuis et al. 2005). There has been a long-standing debate on the impact of patents and other IP
42 rights on innovation and economic development (Hall and Helmers 2019; Machlup 1958). Jaffe and
43 Lerner (2004) and Bessen & Meurer (2009) highlight how IP rights also hamper innovation in a variety
44 of ways. Other more specific contributions in the literature focus on specific factors. For example,
45 Shapiro (2001) discusses patent thickets, where overlapping sets of patent rights mean that those
46 seeking to commercialize new technology, need to obtain licenses from multiple patentees. Heller and
47 Eisenberg (1998) argue that a ‘tragedy of the anticommons’ is likely to emerge when too many parties
48 obtain the right to exclude others from using fragmented and overlapping pieces of knowledge, with

1 ultimately no one having the effective privilege of using the results of biomedical research. Reitzig et
2 al. (2007) describe the damaging effects of extreme business strategies employing patents, such as
3 patent trolling.

4 IP protection and enforcement in general may have different impacts on economic growth in different
5 types of countries (*limited evidence, high agreement*). There has been a significant degree of
6 harmonisation and cooperation between national IP systems over time. The most recent milestone is the
7 1994 WTO agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS Agreement),
8 entered into by all members of the World Trade Organisation (WTO), and which sets down minimum
9 standards for the regulation by national governments of many forms of intellectual property as applied
10 to nationals of other WTO member nations (WTO 1994). Developing countries successfully managed
11 to include some flexibilities into TRIPS both in terms of timing of legislative reform and in terms of
12 the content of the reforms. In an attempt to understand the effects of the introduction of TRIPS, Falvey
13 et al. (2006) find that the effect of IP protection on growth is positively and significantly related to
14 growth for low- and high-income countries, but not for middle-income countries. They argue that low-
15 income countries benefit from increased technology flows, but middle-income countries may have
16 offsetting losses from the reduced scope for imitation. Note that Falvey et al. (2006) do not break down
17 their results in different technological areas and they do not focus on innovation, but instead growth. It
18 has been argued that the increasingly globalised IP regime through initiatives like the TRIPS agreement
19 will diminish prospects for technology transfer and competition in developing countries, particularly
20 for several important technology areas related to meeting sustainable development needs (Maskus and
21 Reichman 2017).

22 In principle, patent holders are not required to take their protected invention into use, and neither have
23 the obligation to allow (i.e., license) others to use the inventions in question (*high evidence, high*
24 *agreement*). Studies have shown that the way patent holders use their patent differs considerably across
25 industrial sectors: in pharmaceuticals, patents are typically used to be the only producer of a certain good
26 (and obtain monopoly rents), while in industries like computers, semiconductors, and communications,
27 patents are often used to strengthen positions in cross-licensing negotiations and to generate licensing
28 income (Cohen et al. 2000; Foray 2004). There are also companies that predominantly obtain patents
29 for defensive reasons: they seek freedom to design and manufacture, and by owning a patent portfolio
30 themselves, they hope to prevent that they become the target of litigation by other patent holders (Hall
31 and Ziedonis 2001). Patents are often used strategically to impede the development and diffusion of
32 competing, alternative products, processes or services, by employing strategies known as ‘blanketing’
33 and ‘fencing’ (Grandstrand 2000), although the research is not specific to the climate space.

34 There are notable but specific exceptions to the general principle that patent holders are not obliged to
35 license their patent to others. These exceptions include the compulsory license, Fair, Reasonable and
36 Non-discriminatory (FRAND) policies, and statement on licences of right (*high evidence, high*
37 *agreement*). While patent holders are, as stated above, in principle free to choose not to license their
38 innovation, there are three important exceptions to this. First, most national patent laws have provisions
39 for compulsory licensing, meaning that a government allows someone else to produce a patented
40 product or process without the consent of the patent holder, or plans to use the patent-protected
41 invention itself (WTO 2020). Compulsory licenses may be issued in cases of public interest or events
42 of abuse of the patent (Biadgleng 2009; World Intellectual Property Organization 2008). Compulsory
43 licensing is explicitly allowed in the WTO TRIPS agreement, and its use in context of medicine (for
44 instance to control diseases of public health importance, including HIV, tuberculosis and malaria) is
45 further clarified in the ‘DOHA Declaration’ from 2001 (Reichman 2009; WHO 2020). Second,
46 standard-setting organisations have policies to include patented inventions in their standards only if the
47 patent holder is willing to commit FRAND licensing conditions for those patents (Contreras 2015).
48 While a patent holder can still choose not to make such a commitment, by doing so, its patent is not

1 candidate anymore for inclusion in the standard. In the (many) fields where standards are of key
2 importance, it is very unusual for patent holders not to be willing to enter into FRAND commitments
3 (Bekkers 2017). Third, when a patent holder, at the time of filing at the patent office, opts for the
4 “licence of right” regime, in return for reduced patent fees, it enters into a contractual agreement that
5 obliges to license the patent to those that request it. While not all national patent systems feature this
6 regime, it is a feature present in the new European Community patent (EPO 2017), and may therefore
7 increase in importance.

8 For a discussion on the impact of IPR on international technology diffusion, see Box 16.9 in Section
9 16.5.

10

11 **16.4.7 Sub-national innovation policies and industrial clusters**

12 Research examining the impacts of sub-national policies on innovation and competitiveness is sporadic
13 – regional variations have been quantitatively assessed in US or China, or with case studies in these and
14 other countries. Research on wind energy in the United States, distributed PV balance of systems in
15 China, and renewable energy technologies in Italy have found that policies that incentivised local
16 demand were associated with inducing innovation, measured with patents (Fu et al. 2018; Gao and Rai
17 2019; Corsatea 2016). Different policies may have different impacts – for example, in the United States
18 state-level tax incentives and subsidies induced innovation within the state; but for renewable portfolio
19 standards policies in other states were associated with innovation, because of impact on demand, but
20 own-state policies were not (Fu et al. 2018). Research has also noted that the outcomes of policy and
21 regulation on innovation are spatially heterogenous, because of differences in local planning authorities
22 and capabilities (Song et al. 2019; Corsatea 2016).

23 Sub-national deployment policies have been associated with different impact on competitiveness
24 metrics (*limited evidence, medium agreement*). Research on green jobs show positive association
25 between sub-national policies and green jobs or green firms at the metropolitan level as well as the state
26 of provincial level, in both China and the United States (Yi 2013; Yi and Liu 2015; Lee 2017), while
27 others find no impact of renewable portfolio standards on green job growth in the state (Bowen et al.
28 2013). Other examples of competitiveness are in the impact of regional green industrial policy in
29 Brazil’s Rio Grande do Sul region in attracting auctioned contracts for wind energy (Adami et al. 2017)
30 or in the changes in net positive state revenues associated with removing tax incentives for wind
31 producers in Idaho in the US (Black et al. 2014).

32 Sub-national policies also directly support innovation and competitiveness through green incubators
33 and direct grants or R&D funding for local companies working on clean energy, intending to promote
34 local economic development (*limited evidence, medium agreement*). The literature on the impacts of
35 such policies on innovation and competitiveness is sparse. Some case studies and program evaluation
36 reports, primarily in the United States, have identified the impacts of sub-national policies on
37 competitiveness — for example, job creation from direct R&D funding in North Carolina (Hall and
38 Link 2015), perceptions for local industry development and support for follow-on financing for
39 companies receiving state-funded grants in Colorado (Surana et al. 2020b), and return on investments
40 for the state in research and innovation spending from the New York state’s energy agency (NYSERDA
41 2020). There is a general paucity of metrics on innovation and competitiveness for systematic
42 assessments of such programs in developed countries, and even more so in India and other developing
43 countries where such programs have been increasing (Surana et al. 2020a; Gonsalves and Rogerson
44 2019).

45 Although states and local governments increasingly support clean energy deployment as well as directly
46 support innovation given its link with economic development goals, there is a lack of systematic
47 research on the impacts of these policies at the subnational level. More research—both qualitative and

1 quantitative, and in both developed and developing countries—is needed to systematically develop
2 evidence on these impacts and to understand the reasons behind regional differences in terms of the
3 type of policy as well as the capabilities in the region.

5 **16.4.8 System-oriented policies and instruments**

6 Although previous sections summarised the research disentangling the role of individual policies in
7 advancing or hindering innovation (as well as impacts on other objectives), other research has tried to
8 characterise the impact of a policy mix on a particular outcome. Although the outcome studied was not
9 innovation, but diffusion (technology effectiveness is in the set of criteria outlined above), it seems
10 relevant to discuss overall findings. Reviewing renewable energy policies in nine OECD countries,
11 research concludes that, over time, a broad set of policies characterized by a ‘balance’ metric has been
12 put in place. This research also identifies a significant negative association between the balance of
13 policies in renewable energy and the diffusion of total renewable energy capacity but no significant
14 effect of the overall intensity (coded as the 46 weighted average of six indicators) on renewable capacity
15 (Schmidt and Sewerin 2019), indicating that a neutral conception of balance across all possible policies
16 may not be desirable and that policy mix intensity by itself does not explain technology diffusion.

17 A growing body of research aims to understand how different policies interact and how to characterise
18 policy mixes (del Río and Cerdá 2017; del Río 2010; Howlett and del Río 2015; Rogge and Reichardt
19 2016). The empirical impact on the innovation outcomes is not yet discussed. A more detailed
20 discussion of this literature is located in Chapter 13.

21 An emerging stream of research in complex systems has suggested that relatively small changes in
22 policy near a possible tipping point in climate impacts in areas including changing strategies related to
23 investments in innovation, could trigger large positive societal feedbacks in the long term (Farmer et
24 al. 2019; Otto et al. 2020a).

26 **16.5 International technology transfer and cooperation for transformative 27 change**

28 This section covers international transfer and cooperation in relation to climate-related technologies,
29 “the flows of know-how, experience and equipment for mitigating and adapting to climate change
30 amongst different stakeholders” (IPCC 2000) as well as innovation to support transformative change
31 compared to the AR5 (IPCC 2014) and the SR1.5 (IPCC 2018a). This complements the discussion on
32 international cooperation on science and technology in Chapter 14.

33 This section first outlines the needs for and opportunities of international transfer and cooperation on
34 low-emission technologies. It then describes the main objectives and roles of these activities, and then
35 reviews recent institutional approaches within and outside the UNFCCC to support international
36 technology transfer and cooperation. Finally, it discusses emerging ideas on international transfer and
37 cooperation on technology, and possible modifications to support the achievement of climate change
38 and sustainable development goals, building up to Section 16.6.

40 **16.5.1 International cooperation on technology development and transfer: needs and 41 opportunities**

42 With the submission of their NDCs as part of the Paris Agreement, most developing countries are now
43 engaged in climate mitigation and adaptation. While technology is seen as one of the ‘means of

1 implementation' of climate action, developing countries often have relatively limited technology
2 innovation capabilities, which requires them to access technologies developed in higher-income
3 countries with stronger innovation systems (Popp 2011; Binz et al. 2012; Urban 2018). In many cases,
4 these technologies require adaptation for the local context and needs (Sagar 2009; Anadon et al. 2016b),
5 and, once again, innovation capabilities are required to suitably adapt these technologies for local use
6 and also to create new markets and business models that are required for successful deployment
7 (Ockwell et al. 2015; Ockwell and Byrne 2016; Sagar 2009). This can lead to dependencies on foreign
8 knowledge and providers (Ockwell and Byrne 2016), negative impacts in terms of higher costs
9 (Huenteler et al. 2016a), and balance of payments constraints and vulnerability to external shocks
10 (Ebeling 2020).

11 The climate technology transition can also yield other development benefits, for instance better health,
12 increased energy access, poverty alleviation and economic competitiveness (Deng et al. 2018a),
13 including industrial development, job creation and economic growth (Altenburg and Rodrik 2017;
14 Porter and Van der Linde 1995; Lema et al. 2020; Pegels and Altenburg 2020) (See Section 16.6). The
15 growing complexity of technologies and global competition have made the development of a
16 technology into a globalized process involving the flow of knowledge and products across borders
17 (Koengkan et al. 2020; Lehoux et al. 2014). For instance, in production of electronics, Asian economies
18 have captured co-location synergies and dominate production and assembly of product components,
19 whereas American firms have adopted “design-only” strategies (Tassey 2014). In the context of
20 renewable energy technologies, “green global division of labour” has been observed, with countries
21 specialising in investments in R&D, manufacturing or deployment of renewables (Lachapelle et al.
22 2017). In the case of solar PV, for example, while many of the technical innovations emerged from the
23 US, Japan and China emphasized the manufacture of physical modules (Deutch and Steinfeld 2013)
24 (see also Box 16.4).

25 Such globalization of production and supply chains opens up economic development opportunities for
26 developing countries (Lema et al. 2020). At the same time, not all countries benefit from the
27 globalisation of innovation, as barriers remain related to finance, environmental performance, human
28 capabilities and cost (Egli et al. 2018; Weiss and Bonvillian 2013), with developing countries being
29 particularly disadvantaged at leveraging these opportunities. The gap in low-carbon technology
30 innovation between countries appears to have been reducing only amongst OECD countries (Yan et al.
31 2017; Du and Li 2019; Du et al. 2019) and the lower-income countries are not able to benefit as much
32 from low-carbon technologies. For instance, in the case of agriculture, Fuglie (2018) notes out that
33 international R&D spillovers seem to have benefited developed countries more than developing
34 countries. Gross et al (2018) also argue that the development timescales for new energy technologies
35 can extend up to 70 years, even within one country, and recommend that innovation efforts be balanced
36 between on the one hand commercialising already low-emission technologies in the demonstration
37 phase, and diffusing them globally, and on the other hand early-stage R&D spending.

38 Thus international cooperation on technology development and transfer can enable developing
39 countries to achieve their climate goals more effectively, while also addressing other sustainable
40 development goals, taking advantage, where possible, of the globalization of innovation and production
41 (Lema et al. 2020). Earlier assessments in the AR5 and SR1.5 have made it clear that international
42 technology transfer and cooperation could play a role in climate policy at both the international and the
43 domestic policy level (IPCC 2018b; Stavins et al. 2014; Somanathan et al. 2014) and for low-carbon
44 development at the regional level (Agrawala et al. 2014). The Paris Agreement also reflects this view
45 by noting that countries shall strengthen cooperative action on technology development and transfer
46 regarding two main aspects: 1) promoting collaborative approaches to research and development and
47 2) facilitating access to technology to developing country Parties (UNFCCC 2015). Furthermore, both

1 in literature and in UNFCCC deliberations, South-South technology transfer is highlighted (Khosla et
2 al. 2017) as a complement to the transfer of technology and know-how from North to the South.

3 This is consistent with literature that suggests that GHG mitigation in developing countries can be
4 enhanced by (1) technology development and transfer collaboration and a ‘needs-driven’ approach, (2)
5 development of the specific types of capacity required across the entire innovation chain and (3)
6 strengthening of the coordination and agendas across and between governance levels (including
7 domestic and international levels) (Upadhyaya et al. 2020; Zhou 2019; Khosla et al. 2017).

8

9 **16.5.2 Objectives and roles of international technology transfer and cooperation efforts**

10 International efforts involving technology transfer can have different objectives and roles. These
11 include access to knowledge and financial resources as well as promotion of new industries in both the
12 developed and recipient country (Huh and Kim 2018). Based on an econometric analysis of
13 international technology transfer factors and characteristics of Clean Development Mechanism (CDM)
14 projects, Gandenberger et al (2016) find that complexity and novelty of technologies explain whether
15 CDM project includes hardware technology transfer, and that factors like project size and absorptive
16 capacity of the host country do not seem to be drivers. Halleck Vega and Mandel (2018) argue that
17 ‘long-term economic relations’, for instance being part of a customs union, affects technological
18 diffusion between countries for the case of wind energy, and indicate that this has resulted in low-
19 income countries being largely overlooked.

20 There is some literature studying whether technology cooperation could complement or replace
21 international cooperation based on emission reductions, such as in the Kyoto Protocol, and whether that
22 would have positive impacts on climate change mitigation and compliance. A handful of papers
23 conducted game-theoretic analysis on technology cooperation, sometimes as an alternative for
24 cooperation on emission reductions, and found partially positive effects (Rubio 2017; Narita and
25 Wagner 2017; Bosetti et al. 2017; Verdolini and Bosetti 2017). However, Sarr and Swanson
26 (2017) model that, due to the rebound effect, technology development and transfer of resource-saving
27 technologies may not lead to envisioned emission reductions.

28 While technology cooperation can be aimed at emission reduction through mitigation projects, as
29 indicated above, not all cooperative actions directly result in mitigation outcomes. Overall, technology
30 transfer broadly has focused on i) enhanced climate technology absorption and deployment in
31 developing countries and ii) enhanced RD&D through cooperation and knowledge spill-overs.

32 **16.5.2.1 Enhancing low-emission technology uptake in developing countries**

33 Real-world outcomes in terms of low-emission technology deployment in developing countries may
34 vary significantly depending on both the nature of the international engagement and the domestic
35 context. While there have been some success in the enhancement of technology deployment through
36 technology transfer in some developing countries (de la Tour et al. 2011; Zhang and Gallagher 2016),
37 many others, and particularly least-developed countries, are lagging behind (Glachant and
38 Dechezleprêtre 2017). They indicate that this is due to the lack of participation in economic
39 globalisation and that climate negotiations could facilitate technology transfer to those countries
40 through the creation of global demand for low-emission technologies through stronger mitigation
41 targets that will result in lowering of costs and therefore enhanced technology diffusion. A broader
42 perspective presents a host of other factors that govern technology diffusion and commercialization in
43 developing countries, including, investment; social, cultural and behavioural, marketing and market
44 building; macroeconomics; and support policy (Bakhtiar et al. 2020). Ramos Mejía et al (2018) indicate
45 that the governance of low-emission technology transfer and deployment in developing countries is
46 frequently negatively affected by a mixture of well- and ill-functioning institutions, in a context of, for
47 instance, market imperfection, clientelist and social exclusive communities and patrimonial and/or

1 marketized states. Furthermore, existing interests, such as fossil fuel production, may also impede the
2 deployment of low-emission technologies, as highlighted in case studies of Vietnam and Indonesia
3 (Dorband et al. 2020; Ordonez et al. 2021). It is for such reasons that both domestic efforts and
4 international engagement are seen as necessary to facilitate technology transfer as well as deployment
5 in developing countries (Boyd 2012). The same has been seen as true in the case of agriculture where
6 the very successful international research efforts of the CGIAR (with remarkably favourable benefit-
7 cost ratios (Alston et al. 2021) were complemented by the national agricultural research systems for
8 effective uptake of high-yielding varieties of crops (Evenson and Gollin 2003).

9 One key area for underpinning effective technology uptake in developing countries relates to
10 capabilities for managing technological change that includes the capabilities to innovate, implement,
11 and undertake integrated planning. There is much research to indicate that the ability of a country's
12 firms to adopt new technologies is determined by its absorptive capacity, which includes its own R&D
13 activities, human capacity (e.g., technical personnel), government involvement (including institutional
14 capacity), and the infrastructure in the country (Kumar et al. 1999), and that knowledge and capacity
15 are part of the 'intangible assets' or the 'software' of a firm or a country (Corsi et al. 2020; da Silva et
16 al. 2019; Ockwell et al. 2015). For sustainable development, capacity to plan in an integrated way and
17 implement the SDGs (Elder et al. 2016; Khalili et al. 2015), including using participatory approaches
18 (Disterheft et al. 2015), are conditional means of implementation. It also is argued that, if human capital
19 were at the focus of international climate negotiations as well as national climate policy, it could change
20 the political economy in favour of climate mitigation, which is needed for developing such capabilities
21 in advance to keep up with the required speed of transformation (Hsu 2017; Upadhyaya et al. 2020;
22 Ockwell et al. 2015; IPCC 2018b). Halleck-Vega et al (2018), in a global analysis of wind energy using
23 econometric analysis, lend quantitative credibility to the claim that a technology skill base is a key
24 determinant of technological diffusion. Activities to enhance capabilities include informational
25 contacts, research activities, consulting, education & training and activities related to technical facilities
26 (Huh and Kim 2018; Khan et al. 2020).

27 There are multiple studies drawing on empirical work also support this conclusion. For South-South
28 technology transfer between India and Kenya, not just technical characteristics, but also mutual learning
29 on how to address common problems of electricity access and poverty, was suggested as an important
30 condition for success (Ulsrud et al. 2018). Specifically for Africa, Olawuyi (2018) discusses the
31 capability gap in Africa, despite decades of technology transfer efforts under various mechanisms and
32 programmes of the UNFCCC. The study suggests that barriers need to be resolved by African countries
33 themselves, in particular inadequate access to information about imported climate technologies, lack of
34 domestic capacities to deploy and maintain imported technologies, the weak regulatory environment to
35 stimulate clean technology entrepreneurship, the absence or inadequacy of climate change laws, and
36 weak legal protection for imported technologies. Moreover, Ziervogel et al (2021) indicate that for
37 transformative adaptation, transdisciplinary approaches and capacity building shifting "the co-creation
38 of contextual understandings" instead of top-down transferal of existing knowledge would deliver better
39 results. Despite the understanding of the importance of the capacity issue, significant gaps still remain
40 on this front (Technology Executive Committee 2019); see also 16.5.4).

41 **16.5.2.2 Enhancing RD&D and knowledge spill-overs**

42 As mentioned earlier, RD&D can aid both the development of new technologies as well as their
43 adoption for new use contexts. Therefore it is not surprising that international cooperation on RD&D is
44 identified as a mechanism to promote low-carbon innovation (see, for example, Suzuki (2015),
45 Technology Executive Committee (2021), Mission Innovation (2019)). This has resulted in a variety of
46 international initiatives to cooperate on technology in order to create knowledge spill-overs and develop
47 capacity. For example, the UNFCCC Technology Mechanism, amongst other things, aims to facilitate
48 finance for RD&D of climate technologies by helping with readiness activities for developing country

1 actors. In particular preparing early-stage technologies for a smoother transition to deployment and
2 commercialisation has been emphasised in the context of the Technology Executive Committee
3 (Technology Executive Committee 2017). There are numerous programmes, multilateral, bilateral and
4 private, that have facilitated RD&D, biased mostly towards mitigation (as opposed to adaptation)
5 activities, and many programmes that seemed to be about RD&D were in reality dialogues about
6 research coordination (Ockwell et al. 2015). There also are a variety of possible bilateral and multilateral
7 models and approaches for engaging in joint R&D (Mission Innovation 2019). An update by the
8 Technology Executive Committee (2021) reviewing good practices in international cooperation of
9 technology confirmed the conclusions of Ockwell et al(2015), and moreover highlighted that most
10 initiatives are led by the public sector, and that the private sector tended to get involved only in
11 incubation, commercialisation and diffusion phases. It also concluded that, although participation of
12 larger, higher-income developing countries seems to have increased, participation of least-developed
13 countries is still very low.

15 **16.5.3 International technology transfer and cooperation: recent institutional** 16 **approaches**

17 In the sections below, the literature on various categories of international technology cooperation and
18 transfer is discussed.

19 ***16.5.3.1 UNFCCC technology and capacity building institutions***

20 Technology development and transfer are a part of the UNFCCC since its agreement in 1992 and has
21 undergone discussions and developments in the context of the international climate negotiations ever
22 since, as assessed in AR5 (Stavins et al. 2014). The support on "Technology Needs Assessment" to
23 developing countries was the first major action undertaken by the UNFCCC, and has undergone
24 different cycles of learning (Nygaard and Hansen 2015; Hofman and van der Gaast 2019). Since 2009,
25 the UNFCCC discussions on technology development and transfer have focussed on the Technology
26 Mechanism under the Cancun Agreements of 2010, which can be seen as the global climate governance
27 answer to redistributive claims by developing countries (McGee and Wenta 2014). The Technology
28 Mechanism consists of a Technology Executive Committee (TEC) and a Climate Technology Centre
29 and Network (CTCN). An independent review of CTCN evaluated it on five dimensions – relevance,
30 effectiveness, efficiency, impacts and sustainability – indicated that the organization is achieving its
31 mandate in all these dimensions, although there are some possible areas of improvement. The review
32 also specifically noted that “the lack of predictability and security over financial resources significantly
33 affected the CTCN’s ability to deliver services at the expected level, as did the CTCN’s lack of human
34 and organizational resources and the capacity of NDEs.” (Technology Executive Committee 2017). The
35 CTCN has overcome some of the limitations imposed by resource constraints by acting as a matchmaker
36 from an open-innovation perspective (Lee and Mwebaza 2020). The lack of financial sustainability of
37 the CTCN has been a recurring issue, which may potentially be resolved by deepening the linkage
38 between the CTCN and GCF (Oh 2020). In the meanwhile, the GCF is planning to establish the Climate
39 Innovation Facility to support and accelerate early-stage innovations and climate technologies through
40 the establishment of regional innovation hubs and climate accelerators as well as a climate growth fund
41 (Green Climate Fund 2020).

42 The ‘technology’ discussion has been further strengthened by the Paris Agreement, in which Article 10
43 is fully devoted to technology development and transfer (UNFCCC 2015). However, the political
44 discussions around technology continue to be characterised by viewing technology mostly as hardware
45 (Haselip et al. 2015), and relatively limited in scope (de Coninck and Sagar 2017). The workplans of
46 the Technology Executive Committee (TEC) and the CTCN do, however, indicate a broadening of the
47 perspective on technology (CTCN 2019; Technology Executive Committee 2019).

1 Since the Kyoto Protocol’s Clean Development Mechanism (CDM) has been operational, studies have
2 assessed its hypothesised contribution to technology transfer, including transfer of knowledge. Though
3 not an explicit objective of the CDM, numerous papers have investigated whether CDM projects
4 contribute to technology transfer (Michaelowa et al. 2019). The literature varies in its assessment. Some
5 find extensive use of domestic technology and hence lower levels of international technology transfer
6 (Doranova et al. 2010), while other indicate that around 40% of projects feature hardware or other types
7 of international transfer of technology (Murphy et al. 2015; Seres et al. 2009), depending on the nature
8 of technology, the host country and region (Cui et al. 2020) and the project type (Karakosta et al. 2012).
9 Although the CDM would generally be positively evaluated on the technology transfer contribution, it
10 was also regarded critically as the market-responsiveness and following of export implies a bias to
11 larger, more advanced economies rather than those countries most in need of technology transfer
12 (Gandenberger et al. 2016), although some countries have managed to correct that by directing the
13 projects, sub-nationally, to provinces with the greatest need (Bayer et al. 2016). Also, the focus on
14 hardware transfer of technology in evaluations of technology transfer under the CDM has been criticised
15 (Michaelowa et al. 2019; Haselip et al. 2015). Indeed, although many studies do go beyond hardware
16 in their evaluations (e.g. Murphy et al (2015)), the degree to which the project leads to a change in the
17 national system of innovation or institutional capacity development is not commonly assessed, or
18 assessed as limited (de Coninck and Puig 2015).

19 There is significantly less literature on capacity building under the UNFCCC, especially as it relates to
20 managing the technology transition. D’Auvergne and Nummelin (2017)(D’Auvergne and Nummelin
21 2017), in a legal analysis, indicate the nature, scope and principles of Article 11 on capacity building of
22 the Paris Agreement as being demand- and country-driven, following a needs approach, fostering
23 national, subnational and local ownership, and being iterative, incorporating the lessons learned, as well
24 as participatory, cross-cutting and gender-response. They also highlight that it is novel that least-
25 developed countries and SIDS are called out as the most vulnerable and most in need of capacity
26 building, and that it raises a “legal expectation” that all parties “should” cooperate to enhance the
27 capacity in developing countries to implement the Paris Agreement. These aspects are reflected in the
28 terms of reference of the Paris Committee on Capacity Building (PCCB) that was established in 2015
29 at the 21st Conference of the Parties (UNFCCC 2016; D’Auvergne and Nummelin 2017), which was
30 extended by five years at the 25th Conference of the Parties in 2019 (UNFCCC 2020a,b). In its work
31 plan for 2020-2024, amongst other things, it aims to “identifying capacity gaps and needs, both current
32 and emerging, and recommending ways to address them”.

33 An example of how innovative technologies combined with capacity development and institutional
34 innovation is combined in the context of adaptation to extreme weather in SIDS can be found in Box
35 16.8.

36

37 **START BOX 16.8 HERE**

38 **Box 16.8 Capacity building and innovation for early warning systems in Small Island**
39 **Developing States**

40 One of the areas of international cooperation on capacity building is adaptation, which has been
41 highlighted by both the Technology Executive Committee (Technology Executive Committee 2015;
42 Ockwell et al. 2015) and the Paris Committee on Capacity Building (UNFCCC 2020b) as an area where
43 capacity gaps remain, especially in Small Island Developing States (SIDS).

44 While adaptation was initially conceived primarily in terms of infrastructural adjustments to long-term
45 changes in average conditions (e.g., rising sea levels), a key innovation in recent years has been to
46 couple such long-term risk management to existing efforts to manage disaster risk, specifically
47 including early warning systems enabling early action in the face of climate- and weather-risk at much

1 shorter timescales (e.g., IPCC 2012), with potentially significant rates of return (e.g., Rogers and
2 Tsirkunov 2010; Hallegatte 2012; Global Commission on Adaptation 2019).

3 In recent years, deliberate international climate finance investments have focused on ensuring that
4 developing countries (and especially SIDS and LDCs) have access to improvements in
5 hydrometeorological observations, modelling, and prediction capacity, sometimes with a particular
6 focus on the people intended to benefit from the information produced (e.g., CREWS 2016). For
7 instance, on the Eastern Caribbean SIDS of Dominica, researchers took a community-based approach
8 to identify the mediating factors affecting the challenges to coastal fishing communities in the aftermath
9 of two extreme weather events (in particular hurricane Maria in 2017) (Turner et al. 2020). Adopting
10 an adaptive capacity framework (Cinner et al. 2018), they identified ‘intangible resources’ that people
11 relied on in their post-disaster response as important for starting up fishery, but also went beyond that
12 framework to conclude that the response ability on the part of governmental organisations as well as
13 other actors (e.g. fish vendors) in the supply chain is also a requirement for rebuilding and restarting
14 income-generating activity (Turner et al. 2020). Numerous other studies have highlighted capacity
15 building as adaptation priorities (Williams et al. 2020; Kuhl et al. 2020; Vogel et al. 2020; Basel et al.
16 2020; Sarker et al. 2020).

17 One of several helpful innovations in these efforts is impact-based forecasting (Harrowsmith et al.
18 2020), which provides forecasts targeted at the impact of the hazard rather than simply the
19 meteorological variable, enabling a much easier coupling to early action in response to the information,
20 enabling a more appropriate response afterwards. Automatic responses to warnings have also been
21 adopted in the humanitarian field for anticipatory action ahead (rather than simply in response to)
22 disasters triggered by natural hazards (Coughlan de Perez et al. 2015), resulting in a rapid scale-up of
23 such anticipatory financing mechanisms to tens of countries over the past few years, and emerging
24 evidence of its effectiveness. Still, the response is lacking in coherence and comprehensiveness,
25 resulting in calls for a more systematic evidence agenda for anticipatory action (Weingärtner et al.
26 2020).

27 **END BOX 16.8 HERE**

28

29 From the broader assessment above, despite limitations of available information, it is clear that the
30 number of initiatives and activities on international cooperation and technology transfer and capacity
31 building seem to have been enhanced since both the Cancun Agreements and the Paris Agreement
32 (Technology Executive Committee 2021). However, given the complexity and magnitude of the
33 requirements in terms of coverage of activities, the amount of committed funding, and effectiveness,
34 much more can be done. Some assessments of UNFCCC instruments specifically for technology
35 transfer to developing countries had indicated that functions such as knowledge development, market
36 formation and legitimacy in developing countries’ low-emission technological innovation systems
37 would need much more support to fulfil the Paris goals. (de Coninck and Puig 2015; Ockwell et al.
38 2015); such areas would benefit from continued attention, given their role in the overall climate
39 technology transition.

40 ***16.5.3.2 International RD&D cooperation and capacity building initiatives***

41 Besides the UNFCCC mechanisms, there are numerous other initiatives that promote international
42 cooperation on RD&D as well as capacity building. Some of them are based on the notion of “mission-
43 oriented innovation policy” (Mazzucato and Semieniuk 2017; Mazzucato 2018), which shapes markets
44 rather than merely correcting market failures.

45 For instance, “Mission Innovation” (MI) is a global initiative consisting of 23 member countries and
46 the European Commission working together to reinvigorate and accelerate global clean energy
47 innovation with the objective to make clean energy widely affordable with improved reliability and

1 secured supply of energy. The goal is to accelerate clean energy innovation in order to limit the rise in
2 the global temperature to well below 2°C. The members to seek to increase public investments in clean
3 energy R&D with the engagement of private sectors, and foster international collaboration amongst its
4 members. A recent assessment shows that, although expenditures are rising, the aims are not met by
5 2020 (Myslikova and Gallagher 2020). Gross et al (2018)caution against too much focus on R&D
6 efforts for energy technologies to address climate change, including Mission Innovation. They argue
7 that given the timescales of commercialisation, developing new technologies now would mean they
8 would be commercially too late for addressing climate change. Huh and Kim (2018) discuss two
9 ‘knowledge and technology transfer’ projects that were eventually not pursued through beyond the
10 feasibility study phase due to cooperation and commitment problems between national and local
11 governments and highlight the need for ownership and engagement of local residents and recipient
12 governments.

13 The intellectual property right regime (see Box 16.9) can be an enabler or a barrier to energy transition.
14 For more background on IPR and impact on innovation, see Section 16.4.6.

15

16 **START BOX 16.9 HERE**

17

Box 16.9 Intellectual property rights (IPR) regimes and technology transfer

18 In the global context of climate mitigation technologies, it has been noted that technologies have been
19 developed primarily in industrialised countries but are urgently required in fast-growing emerging
20 economies (Dechezleprêtre et al. 2011). International technology transfer of such technologies can
21 primarily take place via three channels: (i) trade in goods, where technology is embedded in products;
22 (ii) direct foreign investments (FDI), where enterprises transfer firm-specific technology to foreign
23 affiliates, and (iii) patent licenses, where third parties obtain the right to use technologies. IPRs are
24 relevant for all these three channels.

25 Not surprisingly, then, the role of IPRs in international technology transfer of climate mitigation
26 technologies has been much discussed but also described as particularly controversial (Abdel-Latif
27 2015). The relationships between IP rights, innovation, international technology transfer and local
28 mitigation and adaptation are complex (Maskus 2010; Li et al. 2020; Abdel-Latif 2015) and there is no
29 clear consensus on what kind of an IPR regime will be most beneficial for promoting technology
30 transfer.

31 Several studies argue that, particularly in developing nations, the global IP regime has resulted in
32 delayed access, reduced competition and higher prices (Littleton 2008; Zhuang 2017) and that climate-
33 change-related technology transfer is insufficiently stimulated under the current IPR regime.
34 Compulsory licensing (as already used in medicine) is one of the routes proposed to repair this (Abdel-
35 Latif 2015; Littleton 2008).

36 There is little systematic evidence that patents and other IPRs restrict access to environmentally sound
37 technologies, since these technologies mostly are in sectors based on mature technologies where
38 numerous substitutes among global competitors are available (Maskus 2010). This might however
39 change in the future, for instance with new technologies based on plants, via biotechnologies and
40 synthetic fuels (Maskus 2010), for which Correa et al (2020) already find some evidence.

41 There also is literature that suggests weak IPR regimes have a “strong and negative impact on the
42 international diffusion of patented knowledge” (Dechezleprêtre et al. 2013; Glachant and
43 Dechezleprêtre 2017). Also, patents may support market transactions in technology, including
44 international technology transfer, especially to “middle-income” countries and larger developing
45 countries (Maskus 2010; Hall and Helmers 2019) but LDCs may be better served by building capacity
46 to absorb and implement technology (Sanni et al. 2016; Hall and Helmers 2010; Maskus 2010; Glachant

1 and Dechezleprêtre 2017). It is also argued that it is not even clear that the patent system as it exists
2 today is the most appropriate vehicle for encouraging international access (Sanni et al. 2016; Hall and
3 Helmers 2010; Maskus 2010; Glachant and Dechezleprêtre 2017). Given the large variation in
4 perspectives on the role of IPRs in technology transfer, there is a need for more evidence and analysis
5 to better understand if, and under what conditions, IPRs may hinder or promote technology transfer (see
6 also Technology Executive Committee (2012)).

7 In terms of ways forward to meet the challenge of climate change, different suggestions are made in the
8 context of IPRs that can help to further improve international technology transfer of climate mitigation
9 technologies, including through the TRIPS agreement, by making decisions on IPR to developing
10 countries on a case-by-case basis, by developing countries experimenting more with policies on IPR
11 protection, or through brokering or patent-pooling institutions (Littleton 2009; Dussaux et al. 2018;
12 Maskus and Reichman 2017). Others also suggests that distinctions among country groups be made on
13 basis of levels of technological and economic development, with least developed countries getting
14 particular attention (Abbott 2018; Zhuang 2017).

15 **END BOX 16.9 HERE**

17 **16.5.4 Emerging ideas for international technology transfer and cooperation**

18 As with the broader innovation literature (as highlighted in Section 16.3), and, in fact, drawing on such
19 literature, there has been an emergence of a greater understanding of, and emphasis on, the role of
20 innovation systems (at a national, sectoral, and technological level) as a way to help developing
21 countries with the climate technology transition (Technology Executive Committee 2015; Ockwell and
22 Byrne 2016). This has given rise to several proposals, discussed here and summarised in Figure 16.3.

23 Enhancing deployment and diffusion of climate technologies in developing countries would require a
24 variety of actors with sufficient capabilities (*robust evidence, medium agreement*) (Ockwell et al. 2018;
25 Kumar et al. 1999; Sagar et al. 2009). This may include strengthening existing actors (Malhotra et al.
26 2021), supporting science, technology, and innovation-based start-ups to meet social goals (Surana et
27 al 2020b), and developing entities and programs that are intended to address specific gaps relating to
28 technology development and deployment (Ockwell et al. 2018; Sagar et al. 2009).

29 There also is an increasing emphasis on the relevance of participative social innovation, local grounding
30 and policy learning as a replacement of the expert-led technological change (Kowarsch et al. 2016;
31 Chaudhary et al. 2012; Disterheft et al. 2015). Others have suggested a shift to international innovation
32 cooperation rather than technology transfer, which implies donor-recipient relationship. The notion of
33 innovation cooperation also makes more explicit the focus on innovation processes and systems
34 (Pandey et al. 2021). A broad transformative agenda therefore proposes that contemporary societal
35 challenges are complex and multi-variegated in scope and will require the actions of a diverse set of
36 actors to both formulate and address the policy, implying social, institutional and behavioural changes
37 next to technological innovations are the possible solutions (Geels 2004) (see also Cross-Chapter Box
38 12 in this chapter).

39 Several authors have proposed new mechanisms for international cooperation on technology. Ockwell
40 and Byrne (2016) argue that a role for the UNFCCC Technology Mechanism could be to support climate
41 relevant innovation-system builders (CRIBs) in developing countries, institutions locally that develop
42 capabilities that “form the bedrock of transformative, climate-compatible, technological change and
43 development”. Khan et al (2020) propose a specific variant with universities in developing countries
44 serving as ‘central hubs’ for capacity building to implement the NDCs as well as other climate policy
45 and planning instruments; they also suggest that developing countries outline their capacity building
46 needs more clearly in their NDCs.

1 **16.6 Technological change and sustainable development**

2 This section considers technological innovation in the broader context of sustainable development,
3 recognising that technological change happens within social and economic systems, and therefore
4 technologies are conceived and applied in relation to those systems (Grübler 1998). Simplifications of
5 complex interactions between physical and social systems and incomplete knowledge of technological
6 innovation indirect effects may systematically lead to underestimation of environmental impacts and
7 overestimation of our ability to mitigate climate change (Arvesen et al. 2011; Hertwich and Peters
8 2009).

9 In previous sections, the chapter discussed how a systemic approach, appropriate public policies and
10 international cooperation on innovation can enhance technological innovation. This section provides
11 more details on how innovation and technological change, sustainable development and climate change
12 mitigation intertwine.

13

14 **16.6.1 Linking sustainable development and technological change**

15 Sustainable development and technological change are deeply related (UNCTAD 2019). Technology
16 has been critical for increasing productivity as the dominant driving force for economic growth but also,
17 the concentration of technology in few hands has boosted consumption of goods and services which are
18 not necessarily aligned with sustainable development goals (Walsh et al. 2020). It has been suggested
19 that, in order to address sustainable development challenges, science and technology actors would have
20 to change their relation to policymakers (Ravetz and Funtowicz 1999) as well as the public (Jasanoff
21 2003). This has been further elaborated for the SDGs. The scale and ambition of the SDGs call for a
22 change in development patterns that require a fundamental shift in both current best practices and
23 guidelines for technological and investment decisions and in the wider socio-institutional systems
24 (UNCTAD 2019; Pegels and Altenburg 2020). This is needed as not all innovation will lead to
25 sustainable development patterns (Altenburg and Pegels 2012; Lema et al. 2015).

26 Current Sustainable Development Goals (SDG) implementation gaps reflect, to some extent, inadequate
27 understanding of the complex relationships among the goals (Skene 2020; Waiswa et al. 2019), as well
28 as their synergies and trade-offs, including how they limit the range of responses available to
29 communities and governments, and potential injustices (Thornton and Comberti 2017). These
30 relationships have been approached by focusing primarily on synergies and trade-offs while lacking the
31 holistic perspective necessary to achieve all the goals (Nilsson et al. 2016; Roy et al. 2018).

32 A more holistic framework could envisage the SDGs as outcomes of stakeholder engagement and
33 learning processes directed at achieving a balance between human development and environmental
34 protection (Gibbons 1999; Jasanoff 2003), to the extent that the two can be separated. From a science,
35 technology and innovation (STI) perspective, Fu et al (2019) distinguish three categories of SDGs. The
36 first category comprises those SDGs representing essential human needs for which inputs that put
37 pressure on sustainable development would need to be minimized. These include food (SDG 2), water
38 (SDG 6) and energy (SDG 7) resources, which continue to rely on production technologies and practices
39 that are eroding ecosystem services, hampering the realization of SDG goals 15 (land) and 14 (oceans)
40 (Díaz et al. 2019). The second are those related to governance and which compete with each other for
41 scarce resources, such as infrastructure (SDG 9) and climate action (SDG 13), which require an
42 interdisciplinary perspective. The third category are those that require maximum realization, include no
43 poverty (SDG 1), quality education (SDG 4) and gender equality (SDG 5) (Fu et al. 2019).

44 Resolving tensions between the SDGs requires adoption and mainstreaming of novel technologies that
45 can meet needs while reducing resource waste and improving resource-use efficiency, and while
46 acknowledging the systemic nature of technological innovation, which involve many levels of actors,

1 stages of innovation and scales (Anadon et al. 2016b). Changes in production technology have been
 2 found effective to overcome trade-offs between food and water goals (Gao and Bryan 2017). Innovative
 3 technologies at the food, water and energy nexus are transforming production processes in industrialized
 4 and developing countries, such as developments in agrivoltaics, which is co-development of land for
 5 agriculture and solar with water conservation benefits (Barron-Gafford et al. 2019; Schindele et al.
 6 2020; Lytle et al. 2020), and other renewably powered low- to zero-carbon food, water and energy
 7 systems (He et al. 2019). Silvestre and Țircă (Silvestre and Țircă 2019) indicate that maximising both
 8 social and environmental aims is not possible, but that sustainable innovations include satisfactory
 9 solutions for social, environmental and economic pillars (see Figure 16.4).

10

Social Emphasis	High	SOCIAL INNOVATIONS	SUSTAINABLE INNOVATIONS
		<ul style="list-style-type: none"> -Primary focus is given to the social dimension and associated concerns when developing and/or adopting this type of innovation; -Environmental dimension/concerns and economic dimension/concerns are subservient (i.e., often compromised to maximize social outcome). 	<ul style="list-style-type: none"> -Social, environmental and economic dimensions and their associated concerns are considered in a balanced approach when developing and/or adopting this type of innovation; -There is no maximization opportunities, but satisfactory solutions that allow all the three pillars to be considered simultaneously.

11

12 **Figure 16.4: Considerations and typology of innovations for sustainable development (Silvestre and Țircă**
 13 **2019).**

14 There is evidence that technological changes can catalyse implementation of the reforms needed to the
 15 manner in which goods and services are distributed among people (Fu et al. 2019). A recently developed
 16 theoretical framework based on a capability approach (CA) has been used to evaluate the quality of
 17 human life and the process of development (Haenssger and Ariana 2018). Variations of the CA have
 18 been applied to exploratory studies of the link between technological change, human development, and
 19 economic growth (Mayer 2001; Mormina 2019). This suggests that the transformative potential of
 20 technology as an enabling condition is not intrinsic, but is assigned to it by people within a given
 21 technological context. A failure to recognize and account for this property of technology is a root cause

1 of many failed attempts at techno-fixing sustainable development projects (Stilgoe et al. 2013; Fazey et
2 al. 2020).

3 The basic rationale for governance of technological change is the creation and maintenance of an
4 enabling environment for climate and SDG-oriented technological change (Avelino et al. 2019). Such
5 an environment poses high demands on governance and policy to coordinate with actors and provide a
6 direction for innovation and technological change. Cross-Chapter Box 12 illustrates how the dynamics
7 of socio-technical transitions and shifting development pathways towards sustainable development
8 offer options for policymakers and other actors to accelerate the system transitions needed for both
9 climate change mitigation and sustainable development. Governance interventions to implement the
10 SDGs will need to be operationalized at sub-national, national and global levels and support integration
11 of resource concerns in policy, planning and implementation (UNEP 2015; Williams et al. 2020).

Cross-Chapter Box 12 Transition Dynamics

15 Authors: Anthony Patt (Switzerland), Heleen de Coninck (the Netherlands), Xuemei Bai (Australia),
16 Paolo Bertoldi (Italy), Sarah Burch (Canada), Clara Caiafa (Brazil/the Netherlands), Felix Creutzig
17 (Germany), Renée van Diemen (the Netherlands/United Kingdom), Frank Geels (United Kingdom/the
18 Netherlands), Michael Grubb (United Kingdom), Maria Figueroa (Venezuela/Denmark), Şiir Kilkış
19 (Turkey), Jonathan Köhler (Germany), Catherine Mitchell (United Kingdom), Lars J. Nilsson
20 (Sweden), Patricia Perkins (Canada), Yamina Saheb (France/Algeria), Harald Winkler (South Africa)

21 **Introduction:** Numerous studies suggest that transformational changes would be required in many
22 areas of society if climate change is to be limited to 2°C warming or less. Many of these involve shifts
23 to low carbon technologies, such as renewable energy, which typically involve changes in associated
24 regulatory and social systems; others more explicitly concern behavioural shifts, such as towards plant-
25 based diets or cleaner cooking fuels, or, at the broadest level, a shift in development pathways. Chapter
26 1 establishes an analytic framework focusing on transitions, which chapters 5, 13, 14, 15 and 16 further
27 develop. In this cross-chapter box, we provide a complementary overview of the dynamics of different
28 kinds of transformational changes for climate mitigation and sustainable development. We first focus
29 on insights from socio-technical transitions approaches, and then expand to broader system transitions.

30 **Dynamics of socio-technical transitions:** A large literature documents the processes associated with
31 transformational changes in technology and the social systems associated with their production and use
32 (Köhler et al. 2019; Geels 2019). Transformational technological change typically goes hand-in-hand
33 with shifts in knowledge, behaviour, institutions, and markets (Markard et al. 2012, p. 956; Geels and
34 Schot 2010); stickiness in these factors often keeps society “locked-in” to those technologies already in
35 widespread use, rather than shift to new ones, even those that offer benefits (David 1985; Arthur 1994).
36 Exceptions often follow consistent patterns (Unruh 2002; Geels 2002); since AR5 a growing number
37 of scholars have suggested using these insights to design more effective climate policies and actions
38 (Geels et al. 2017). Chapter 1 (see Section 1.7 and Figure 1.6) represents technology diffusion and a
39 corresponding shift in policy emphasis as a continuous process; it is also useful to identify a sequence
40 of distinct stages that typically occur, associating each stage with a distinct set of processes, challenges,
41 and effective policies (Patt and Lilliestam 2018; Victor et al. 2019). Consistent with elsewhere in this
42 report (section 5.5.2 and SM.5.5.3 in Chapter 5, and section 16.3 in Chapter 16), Cross-Chapter Box 12
43 Figure 1 elaborates four distinct stages. Recognizing that even transformative technologies will
44 eventually be replaced with newer ones, the figure portrays these as occurring in a cycle.

45

Cross-Chapter Box 12, Figure 1 Stages of socio-technical transition processes

The *emergence* stage is marked by experimentation, innovation in the laboratory, and demonstration in the field, to produce technologies and system architectures (Geels 2005a). By its very nature, experimentation includes both successes and failures, and implies high risks. Because of these risks, especially in the case of fundamentally new technologies, government funding for research, development and demonstration (RD&D) projects is crucial to sustaining development (Mazzucato 2015b).

The second stage is *early adoption*, during which successful technologies jump from the laboratory to limited commercial application (Pearson and Foxon 2012). Reaching this stage is often described as crossing the “Valley of Death”, because the cost/performance ratio for these new market entrants is too low for them to appear viable to investors (Murphy and Edwards 2003). A key process in the early adoption phase is induced innovation, a result of incremental improvements in both design and production processes, and of mass-production of a growing share of key components (Grubb et al. 2021; Nemet 2006). There is diversity across classes of technologies, and learning tends to occur faster for technologies that are modular (Wilson et al. 2020), such as photovoltaics, and slower for those that require site- or context-specific engineering, such as in the shift to low carbon materials production (Malhotra and Schmidt 2020). Public policies that create a secure return on investment for project developers can lead to learning associated with industry expansion (See Chapter 16, Figure 16.1); typically these are economically and politically viable when they promote growth within a market “niche”, causing little disruption to the mainstream market (Roberts et al. 2018). Direct support mechanisms, including cross-subsidies, such as feed-in tariffs, and market quotas such as renewable portfolio standards, are effective (Patt and Lilliestam 2018; Geels et al. 2017b; see Chapter 9 for assessment of early adoption policies in the building sector). The value of these policies is less in their immediate emissions reductions, but more in generating the conditions for self-sustaining transformational change to take place as technologies later move from niche to mainstream (Hanna and Victor 2021).

The third stage, *diffusion*, is where niche technologies become mainstream, with accelerating diffusion rates (see Chapter 1, Sections 1.7 and 16.4), and is marked by changes to the socio-technical “regime”, including infrastructure networks, value chains, user practices, and institutions. This stage is often the most visible and turbulent, because more widespread adoption of a new technology gives rise to

1 structural changes in institutions and actors' behaviour (e.g. increased adoption of smart phones to new
2 payment systems and social media), and because when incumbent market actors become threatened,
3 they often contest policies promoting the new technologies (Köhler et al. 2019). In the diffusion stage,
4 policy emphasis is shifted from financial support during the early adoption stage, towards supporting
5 regime-level factors needed to sustain, or cope with, rapid and widespread diffusion (Markard 2018).
6 These factors and policies are context specific. For example, Patt et al. (Patt et al. 2019) document that
7 the policies needed to expand residential charging networks for electric vehicles depend on the local
8 structure of the housing market.

9 The fourth stage is *stabilisation*, in which the new technologies, systems, and behaviours are both
10 standardized and insulated from rebound effects and backsliding (Andersen and Gulbrandsen 2020).
11 Sectoral bans on further investment in high carbon technologies may become politically feasible at this
12 point (Breetz et al. 2018; Economidou et al. 2020). The decline of previously dominant products or
13 industries can lead to calls for policy-makers to help those negatively affected, enabling a just transition
14 (Newell and Simms 2020; McCauley and Heffron 2018). Political opposition to the system
15 reconfiguration that comes with integration and stabilization can also be overcome by offering
16 incumbent actors an attractive exit strategy (de Gooyert et al. 2016).

17 Because different sectors are at different stages of low-carbon transitions, and because the barriers that
18 policies need to address are stage- and often context-specific, effective policies stimulating socio-
19 technical transitions operate primarily at the sectoral level (Victor et al. 2019). This is particularly the
20 case during early adoption, where economic barriers predominate; during diffusion, policies that
21 address regime-level factors often need to deal with cross-sectoral linkages and coupling, such as those
22 between power generation, transportation, and heating (Patt 2015; Bloess 2019; Fridgen et al. 2020).
23 The entire cycle can take multiple decades. However, later stages can go faster by building on the earlier
24 stages' having taken place elsewhere. For example, early RD&D into wind energy took place primarily
25 in Denmark, was followed by early adoption in Denmark, Germany, and Spain, before other countries,
26 including the United States, India, and China leapfrogged directly to the diffusion stage (Lacal-
27 Arántegui 2019; Chaudhary et al. 2015; Dai and Xue 2015). A similar pattern played out for solar power
28 (Nemet 2019b). International cooperation, geared towards technology transfer, capacity and institution-
29 building, and finance, can help ensure that developing countries leapfrog to low-carbon technologies
30 that have undergone commercialization elsewhere (Adenle et al. 2015; Fankhauser and Jotzo 2018)(see
31 also Chapter 5, Box 5.9, Chapter 15, Section 15.5 and Section 16.5 in this chapter)..

32 This report contains numerous examples of the positive feedbacks in the centre of Cross-Chapter Box
33 12, Figure 1, predominantly arising during the early adoption and diffusion stages, and leading to rapid
34 or unexpected acceleration of change. Public acceptance of alternatives for meat leads to firms
35 improving the products, increasing political and economic feedbacks (Chapter 5, Section 5.4, Box 5.5).
36 Declining costs in solar and wind cause new investment in the power generation sector being dominated
37 by those technologies, leading to increased political support and further cost reductions (Chapter 6). In
38 buildings (Chapter 9) and personal mobility (Chapter 10), low-carbon heating systems and electric
39 passenger vehicles are gaining public acceptance, leading to improved infrastructure and human
40 resources, more employment in those sectors, and behavioural contagion. Some have argued that
41 technologies cross societal tipping points on account of these feedbacks (Obama 2017; Sharpe and
42 Lenton 2021).

43 **Dynamics between enabling conditions for system transitions:** Abson et al. (2017) argue that it is
44 possible to make use of “leverage points” inherent in system dynamics in order to accelerate
45 sustainability transitions. Otto et al. (2020b) argue that interventions geared towards the social factors
46 driving change can “activate contagious processes” leading towards the transformative changes
47 required for climate mitigation. These self-reinforcing dynamics involve the interaction of enabling
48 conditions including public policy and governance, institutional and technological innovation capacity,

1 behaviour change, and finance. For example, Mercure et al. (2018) simulated financial flows into fossil-
2 fuel extraction, and showed how investors' taking into account transition risk in combination with
3 technological innovation would lead to the enhancement of investments in low-carbon assets and further
4 enhanced innovation. As another example, behaviour, lifestyle, and policy can also initiate demand-
5 side transitions (Chapter 5) (Tziva et al. 2020), such as with food systems (Rust et al. 2020) (Chapter
6 7, section 7.4.5), and can contribute to both resilience and carbon storage (Sendzimir et al. 2011)
7 (Chapter 16, Box 16.5).

8 In the urban context, the concept of sustainability experiments has been used to examine innovative
9 policies and practices adopted by cities that have significant impact on transition towards low-carbon
10 and sustainable futures (Bai et al. 2010; Castán Broto and Bulkeley 2013). Individual innovative
11 practices can potentially be upscaled to achieve low-carbon transition in cities (Peng and Bai 2018),
12 leading to a process of broadening and scaling innovative practices in other cities (Peng et al.
13 2019). Such sustainability experiments give rise to new actor networks, which in some cases may
14 accelerate change, and in others may lead to conflict (Bulkeley et al. 2014). As in the diffusion phase
15 in Cross-Chapter Box 12, Figure 1, contextual factors play a strong role. Examining historical
16 transitions to cycling across European cities, Oldenziel et al. (2016) found contextual factors including
17 specific configurations of actors to lead to very different outcomes. Kraus and Koch (2021) found a
18 short-term social shock – the COVID crisis – to lead to differential increases in cycling behaviour,
19 contingent on other enabling conditions.

20 **Linking system dynamics to development pathways and broader societal goals:** Transition
21 dynamics insights can be broadened to shifting development pathways. Development paths are
22 characterised by particular sets of interlinking regime rules and behaviours, including inertia and
23 cascading effects over time, and are reinforced at multiple levels, with varied capacities and constraints
24 on local agency occurring at each level (Burch et al. 2014)(See also Cross-Chapter Box 5 in Chapter
25 4). This is also observed by Schot and Kanger (2018), who identify a needed change in a “meta-
26 regime”, crossing sectoral lines in linking value-chains or infrastructure and overall development
27 objectives. In the context of the UN climate change regime, international cooperation can bring together
28 such best practices and lessons learnt (Pandey et al. 2021; Adenle et al. 2015). This is especially relevant
29 for developing countries, which often depend on technologies and financial resources from abroad,
30 witnessing their pace and direction influenced by transnational actors (Bhamidipati et al. 2019;
31 Marquardt et al. 2016), and benefiting little in terms of participating in high value-added activities
32 (Whittaker et al. 2020).

33 System transitions differ according to context, such as across industrialized and developing countries
34 (Ramos-Mejía et al. 2018), and within countries. Lower levels of social capital and trust negatively
35 impact niche commercialization (Lepoutre and Oguntoye 2018). In contexts of poverty and inequality,
36 stakeholders' – including users' – capabilities for meaningful participation are limited and transition
37 outcomes can end up marginalizing or further excluding social groups (Osongo and Schot 2017; Hansen
38 et al. 2018). Many studies of transitions in developing countries make note of the importance of
39 innovation in the informal sector (Charmes 2016, Box 5.10). Facilitating informal sector access to
40 renewable energy sources, safe and sustainable buildings, and finance can advance low-carbon
41 transitions (McCauley et al. 2019; Masuku and Nzewi 2021). Contrary, disregarding its importance can
42 result in misleading or ineffective innovation and climate strategies (Maharajh and Kraemer-Mbula
43 2010; Mazhar and Ummad 2014; de Beer et al. 2016; Masuku and Nzewi 2021).

44 Policies shifting innovation in climate-compatible directions can also reinforce other development
45 benefits, for instance better health, increased energy access, poverty alleviation and economic
46 competitiveness (Deng et al. 2018b; Karlsson et al. 2020; IPCC 2018a). Development benefits, in turn,
47 can create feedback effects that sustain public support for subsequent policies and hence help to secure
48 effective long-term climate mitigation (Meckling et al. 2015b; Geels 2014b; Schmidt and Sewerin

1 2017b; Breetz et al. 2018), increasing legitimacy of environmental sustainability actions (Hansen et al.
2 2018; van Welie and Romijn 2018; Herslund et al. 2018) and addressing negative socio-economic
3 impacts (Eisenberg 2019; McCauley and Heffron 2018; Henry et al. 2020a; Deng et al. 2018b).

4 **Summary and gaps in knowledge:** Strategies to accelerate climate mitigation can be most effective at
5 accelerating and achieving transformative change when they are synchronized with transition processes
6 in systems. They address technological stage characteristics, take advantage of high-leverage
7 intervention points, and respond to societal dynamics (Abson et al. 2017; Köhler et al. 2019; Geels et
8 al. 2017). Gaps in knowledge remain on how to tailor policy mixes, the interaction of enabling
9 conditions, the generalizability of socio-technical transition insights to other types of systems, and how
10 to harness these insights to better shift development pathways.

11 **END CCB 14 HERE**

13 **16.6.2 Sustainable development and technological innovation: Synergies, trade-offs and** 14 **governance**

15 *16.6.2.1 Synergies and trade-offs*

16 Policies that shift innovation in climate compatible directions can promote other development benefits,
17 for instance better health, increased energy access, poverty alleviation and economic competitiveness
18 (Deng et al. 2018a, see also Cross-Chapter Box 12). Economic competitiveness co-benefits can emerge
19 as climate mitigation policies trigger innovation that can be leveraged for promoting industrial
20 development, job creation and economic growth, both in terms of localizing low-emission energy
21 technologies value chains as well as of increased energy efficiency and avoided carbon lock-ins (Section
22 16.4). However, without adequate capabilities, co-benefits at the local level would be minimal, and they
23 would probably materialize far from where activities take place (Vasconcellos and Caiado Couto 2021;
24 Ockwell and Byrne 2016). Innovation and technological change can also empower citizens. Grass-roots
25 innovation promotes the participation of grass-roots actors, such as social movements and networks of
26 academics, activists and practitioners, and facilitate experimenting with alternative forms of knowledge
27 creation (UNCTAD 2019; Seyfang and Smith 2007). Examples of ordinary people and entrepreneurs
28 adopting and adapting technologies to local needs to address locally defined needs have been
29 documented in the development literature (van Welie and Romijn 2018) (See also Box 16.10). Digital
30 technologies can empower citizens and communities in decentralized energy systems contributing not
31 only to a more sustainable but also to a more democratic and fairer energy system (Van Summeren et
32 al. 2021) (See also Cross-Chapter Box 11 in this chapter, and Section 5.4 in Chapter 5).

33 Therefore, even though STI is an explicit focus of SDG 9, it is in fact an enabler of most SDGs
34 (UNCTAD 2019). Striving for synergies between innovation and technological change for climate
35 change mitigation with other SDGs can help to secure effective long-term climate mitigation, as
36 development benefits can create feedback effects that sustain public and political support for subsequent
37 climate mitigation policies (Meckling et al. 2015a; Geels 2014a, also Cross-Chapter Box 12). However,
38 innovation is not always geared to sustainable development, for instance, firms tend to know how to
39 innovate when value chains are left intact (Hall and Martin 2005), which tend to not be the case in
40 systemic transitions.

41 A comprehensive study of these effects distinguishes among "...anticipated-intended, anticipated-
42 unintended, and unanticipated-unintended consequences" (Tonn and Stiefel 2019). Theoretical and
43 empirical studies have demonstrated that unintended consequences are typical of complex adaptive
44 systems, and while a few are predictable, a much larger number are not (Sadras 2020). Even when
45 unintended consequences are unanticipated, they can be prevented through actor responses, for instance
46 rebound effects following the introduction of energy efficient technologies. Other examples of

1 unintended consequences include worse-than-expected physical damage to infrastructure and resistance
2 from communities in the rapidly growing ocean renewable energy sector (Quirapas and Taeihagh 2020),
3 and gaps between expected and actual performance of building integrated photovoltaic (BIPV)
4 technology (Boyd and Schweber 2018; Gram-Hanssen and Georg 2018). In the agricultural sector, new
5 technologies and associated practices that target the fitness of crop pests have been found to favour
6 resistant variants. Unintended consequences of digitalisation are reported as well (Lynch et al. 2019)
7 (see Cross-Chapter Box 11 in this chapter).

8 Innovation and climate mitigation policies can also have negative socio-economic impacts and not all
9 countries, actors and regions around the world benefit equally from rapid technological change
10 (UNCTAD 2019; Eisenberg 2019; McCauley and Heffron 2018; Henry et al. 2020b; Deng et al. 2018a).
11 In fact, socio-technical transitions often create winners and losers (Roberts et al. 2018). Technological
12 change can reinforce existing divides between women and men, rural and urban populations, and rich
13 and poor communities, as older workers displaced by technological change will not qualify for jobs if
14 they were unable to acquire new skills, weak educational systems may not prepare young people for
15 emerging employment opportunities, and disadvantaged social groups, including women in many
16 countries, often have fewer opportunities for formal education (UNCTAD 2019; McCauley and Heffron
17 2018). That is a risk regarding technological change for climate change mitigation, as emerging
18 evidence suggests that the energy transition can create jobs and productivity opportunities in the
19 renewable energy sector, but will also lead to job losses in fossil fuel and exposed sectors (Le Treut et
20 al. 2021). At the same time these new jobs may use more intensively high-level cognitive and
21 interpersonal skills compared to regular, traditional jobs, requiring higher levels of human capital
22 dimensions such as formal education, work experience and on-the-job training (Consoli et al. 2016).
23 Despite the empowerment potentials of decentralized energy systems, not all societal groups are equally
24 positioned to benefit from energy community policies, with issues of energy justice taking place within
25 initiatives, between initiatives and related actors, as well as beyond initiatives (van Bommel and
26 Höffken 2021; Calzadilla and Mauger 2018).

27 The opportunities and challenges of technological change can also differ within country regions and
28 between countries (e.g. García-Casals et al. 2019). Within countries, Vasconcellos and Caiado Couto
29 (2021) show that, in the absence of policies and capacity building activities which promote local
30 recruiting, a significant part of total benefits of wind projects, especially high-income jobs and high
31 value-added activities, is captured by already higher income regions. Between countries, developing
32 countries usually have lower innovation capabilities, which means they need to import low-emission
33 technology from abroad and are also less able to adapt these technologies to local conditions and create
34 new markets and business models. This can lead to external dependencies and limit opportunities to
35 leverage economic benefits from technology transfer (Section 16.5.1).

36 This means that in countries below the technological frontier, the contribution of technological change
37 to climate change mitigation can happen primarily through the adoption and less through the
38 development of new technologies, which can reduce potential economic and welfare benefits from rapid
39 technological change (UNCTAD 2019). The adoption of consumer ICT technologies (Baller et al. 2016)
40 or renewable energy technologies (Lema et al. 2021) cannot bring least developed economies close to
41 the technological frontier without appropriate technological capabilities in other sectors and an enabling
42 innovation system (UNCTAD 2019; Malhotra et al. 2021; Vasconcellos and Caiado Couto 2021; Sagar
43 and Majumdar 2014; Ockwell and Mallett 2012; Ockwell et al. 2018). It has been argued widely that
44 both hard and soft infrastructure, as well as appropriate policy frameworks and capability building,
45 would facilitate developing countries engagement in long-term technological innovation and
46 sustainable industrial development, and eventually in achieving the SDGs (UNCTAD 2019; Ockwell
47 and Byrne 2016; Altenburg and Rodrik 2017).

1 **16.6.2.2 Challenges to governing innovation for sustainable development**

2 Dominant economic systems and centralized governance structures continue to reproduce unsustainable
3 patterns of production and consumption, reinforcing many economic and governance structures from
4 local through national and global scales (Johnstone and Newell 2018). Technological change, as an
5 inherently complex process (Funtowicz 2020), poses governance challenges (Bukkens et al. 2020)
6 requiring social innovation (Repo and Matschoss 2019) (See also Section 5.6 in Chapter 5, and Chapter
7 13).

8 Prospects for effectively governing SDG-oriented technological transformations require at a minimum
9 balanced views and new tools for securing the scientific legitimacy and credibility to connect public
10 policy and technological change in our society (Sadras 2020; Jasanoff 2018). Many frameworks of
11 governance have been proposed, such as reflexive governance (Voss et al. 2006), polycentric
12 governance (Ostrom 2010), collaborative governance (Bodin 2017), adaptive governance (Munene et
13 al. 2018) and transformative governance (Rijke et al. 2013; Westley et al. 2013) (see also Chapters 13
14 and 14).

15 A particular class of barriers to the development and adoption of new technologies comprises
16 entrenched power relations dominated by vested interests that control and benefit from existing
17 technologies (Chaffin et al. 2016; Dorband et al. 2020). Such interests can generate balancing feedbacks
18 within multi-level social-technological regimes that are related to technological lock-in, including
19 allocations of investment between fossil and renewable energy technologies (Unruh 2002; Sagar et al.
20 2009; Seto et al. 2016).

21 Weaker coordination and implementation capacity in some developing countries can undermine ability
22 to avoid trade-offs with other development objectives, like reinforced inequalities or excessive
23 indebtedness and increased external dependency, and can limit the potential of leveraging economic
24 benefits from technologies transferred from abroad (Section 16.5, Cross-Chapter Box 12). Van Welie
25 and Romijn (2018) show that in a low-income setting the exclusion of some local stakeholders from the
26 decision-making process may undermine sustainability transitions efforts. Countries with high levels of
27 inequality can be more prone to elite capture, non-transparent political decision making processes,
28 relations based on clientelism and patronage, and no independent judiciary (Jasanoff 2018), although
29 in particular contexts, non-elites manage to exert influence (Moldaliev and Heathershaw 2020). The
30 dominance of incumbents however implies that sustainable technological transitions could be achieved
31 without yielding any social and democratic benefits (Hansen et al. 2018). In the cultural domain, a
32 recurrent policy challenge that has been observed in most countries is the limited public support for
33 development and deployment of low carbon technologies (Bernauer and McGrath 2016). The
34 conventional approach to mobilizing such support has been to portray technological change as a means
35 of minimizing climate change. Empirical studies show that simply reframing climate policy is highly
36 unlikely to build and sustain public support (Bernauer and McGrath 2016).

37 Finally, there is a link between social and technological innovation; any innovation is grounded in
38 complex socio-economic arrangements, to which governance arrangements would need to respond (see
39 Sections 5.5 and 5.6, Chapter 13, and Cross-Chapter Box 12 in this chapter). Social innovation can
40 contribute to maximizing synergies and minimizing trade-offs in relation to technological innovation
41 and other innovative practices, but for this to materialize, national, regional and local circumstances
42 need to be taken into account and, if needed, changed. Even in circumstances of high capabilities, the
43 extent social innovation might help to promote synergies and avoid trade-offs is not easy to evaluate
44 (Grimm et al. 2013).

16.6.3 Actions that maximise synergies and minimise trade-offs between innovation and sustainable development

Technological innovation may bring significant synergy in pursuing sustainable development goals, but it may also create challenges to the economy, human well-being, and the environment (Thacker et al. 2019; Schillo and Robinson 2017; Walsh et al. 2020). The degree of potential synergies and trade-offs among SDG differs from country to country and over time (see section 16.6.1.1). These potentials will depend upon available resources, geographical conditions, development stage and policy measures. Even though synergies and trade-offs related to technological innovation have received the least attention from researchers (Deng et al. 2018a), literature show that higher synergy was found where countries' policies take into account the linkages between sectors (Mainali et al. 2018). For technology innovation to be effective in enhancing synergies and reducing trade-offs, its role and nature in production and consumption patterns, as well as in value chains and in the wider economy, requires clarification. Technology ownership and control together with its current orientation and focus towards productivity needs to be revised if a meaningful contribution to the implementation of the SDGs in a transformative way is to be achieved (Walsh et al. 2020). Responsible innovation, combining anticipation, reflexivity, inclusion and responsiveness, has been suggested as a framework for conducting innovation (Stilgoe et al. 2013). Also inclusive innovation (Hoffecker 2021) could make sure that unheard voices and interests are included in decision-making, and methods for this have been implemented in practice (Douthwaite and Hoffecker 2017).

There are several examples on how to maximize synergies and avoid or minimize trade-offs when bringing technological innovation to the ground. When implementing off-grid solar energy in Rwanda, synergies were found between 80 of the 169 SDG targets, demonstrating how mainstreaming off-grid policies and prioritising investment in the off-grid sector can realise human development and well-being, build physical and social infrastructures, and achieve sustainable management of environmental resources (Bisaga et al. 2021). Another example is related to wind power in Northeast of Brazil where the creation of direct and indirect jobs has been demonstrated in areas where capabilities are high, as well as associated improvements in wholesale and retail trade and real estate activities, though this also emphasises the need for capacity development along with international collaboration projects (Vasconcellos and Caiado Couto 2021). Other examples are studies raising awareness on solar energy and women empowerment (Winther et al. 2018) and recycling and waste (Cross and Murray 2018).

Other actions with the potential to maximize synergies are those related to community or "grassroot" technological innovation. The importance of the link between technological innovation and community action and its contribution to sustainable development is usually underestimated, and requires further research and, most importantly, its inclusion in the political agenda on sustainable development (Seyfang and Smith 2007). On the other hand, when technological innovation occurs far from where is implemented and participation in the production, and hence training activities of local actors is minimal, co-benefits and synergies among SDGs are limited and usually far below expectations (Vasconcellos and Caiado Couto 2021; Bhamidipati and Hansen 2021). Actions by policymakers that safeguard environmental and social aspects can boost synergies and maximize those co-benefits (Lema et al. 2021). Given that technological change impacts countries, regions and social groups differently, just transition policies can be designed to ensure all regions and communities are able to take advantage of the energy and other transitions (Henry et al. 2020b; McCauley and Heffron 2018).

Box 16.10 provides insights on how a systemic approach to technological innovation can contribute to reconcile synergies and trade-offs to achieve sustainable development and mitigation goals.

START BOX 16.10 HERE

1 out but which innovative public policies (the transfer of property rights over trees from the state to
2 farmers) helped restore (Sendzimir et al. 2011).

3 Rice paddy fields are a major source of methane. Climate change impacts and adaptation strategies can
4 affect rice production and net income of rice farmers. Biochar use in rice paddy fields has been
5 advocated as a potential strategy to reduce GHG emissions from soils, enhance soil carbon stocks and
6 nitrogen retention, and improve soil function and crop productivity (Mohammadi et al. 2020).

7 Contributions of indigenous people (Díaz et al. 2019), heritage agriculture (Koohafkan and Altieri
8 2010) and peasants agroecological knowledge (Holt-Giménez 2002) to technological innovation offer
9 a wide array of options for management of land, soils, biodiversity and enhanced food security without
10 depending on modern, foreign agricultural technologies (Denevan 1995). In farming agriculture and
11 food systems, innovation and technology based on nature could help to reduce climate change impacts
12 (Griscom et al. 2017). Evidence suggests that there are benefits to integrating tradition with new
13 technologies in order to design new approaches to farming, and that these are greatest when they are
14 tailored to local circumstances (Nicholls and Altieri 2018).

15 **END BOX 16.10 HERE**

16

17 **16.6.4 Climate change, sustainability development and innovation**

18 This section gives a synthesis of this chapter on innovation and technology development and transfer,
19 connecting it to sustainable development.

20 In conjunction with other enabling conditions, technological innovation can support system transitions
21 to limit warming, help shift development pathways, and bring about new and improved ways of
22 delivering goods and services that are essential to human well-being (*high confidence*). At the same
23 time, however, innovation can result in trade-offs that undermine both progress on mitigation and
24 progress towards other sustainable development goals. Trade-offs include negative externalities such
25 as environmental impacts and social inequalities, rebound effects leading to lower net emission
26 reductions or even increases in emissions, and increased dependency on foreign knowledge and
27 providers (*high confidence*). Digitalisation, for example, holds both opportunity for emission reduction
28 and emission-saving behaviour change, but at the same time causes significant environmental, social
29 and GHG impacts (*high confidence*).

30 A systemic view of innovation, that takes into account the roles of actors, institutions, and their
31 interactions, can contribute to both enhanced understanding of processes and outcomes of technological
32 innovation, and to interventions and arrangements that can help innovation. It can also play a role in
33 clarifying the synergies and trade-offs between technological innovation and the SDGs. Effective
34 governance and policy, implemented in an inclusive, responsible and holistic way, could both make
35 innovation policy more effective, and avoid and minimise misalignments between climate change
36 mitigation, technological innovation, and other societal goals (*medium evidence, high agreement*).

37 A special feature is the dynamics of transitions. Like other enabling conditions, technological
38 innovation plays both a balancing role, by inhibiting change as innovation strengthens incumbent
39 technologies and practices, and a reinforcing role, by allowing new technologies and practices to disrupt
40 the existing socio-technical regimes (*high confidence*). Appropriate innovation policies can help
41 organise innovation systems better, while other policies (technology push and demand pull) can provide
42 suitable resources and incentives to support and guide these innovation systems towards societally-
43 desirable outcomes, ensure the innovations are deployed at scale, and direct these dynamics not just
44 towards system transitions for climate change mitigation, but also towards addressing other SDGs. This
45 means taking into account the full life-cycle or value chain as well as analysis of synergies and trade-
46 offs.

1 Against this backdrop, international cooperation on technological innovation is one of the enablers of
2 climate action in developing countries on both mitigation and adaptation (*high confidence*). Experiences
3 with international cooperation on technology development and deployment suggest that such activities
4 are most effective when approached as “innovation cooperation” that engenders a holistic, systemic
5 view of innovation requirements, is done in equitable partnership between donors and recipients, and
6 develops local innovation capabilities (*medium evidence, high agreement*).

7 Chapter 17, in particular Section 17.4, connects technological innovation with other enabling
8 conditions, such as behaviour, institutional capacity and multi-level governance, to clarify the actions
9 that could be taken, holistically and in conjunction, to strengthen and accelerate the system transitions
10 required to limit warming to be in line with the Paris Agreement and to place countries in sustainable
11 development pathways.

13 16.7 Knowledge gaps

14 Filling gaps in literature availability, data collection, modelling, application of frameworks and further
15 analysis in several sectors will improve knowledge on innovation and technology development and
16 transfer, including R&D to support policy making in climate change mitigation as well as adaptation.
17 These policies and related interventions need to benefit from data and methodologies for the ex-post
18 evaluation of their effectiveness.

19 This section addresses identified knowledge gaps related to what extent developing countries are
20 represented in studies on innovation and technology development and transfer; to national contexts and
21 local innovation capacity; to potential and actual contributions of businesses; to literature emphasis on
22 mitigation; to indicators to assess innovation systems; to non-technical barriers for the feasibility of
23 decarbonisation pathways; to the role of domestic IPR policy; to digitalisation in low-emissions
24 pathways; to the compliance of Paris Agreement in regard to technology and capacity building.

25 One of knowledge gap identified when assessing the literature is on the representation of developing
26 countries in studies on innovation and technology development and transfer. This includes the
27 conceptual core disciplines of the economics of innovation, innovation systems and sustainability
28 transitions. This goes both for studies on developing countries, and for authors originating from, or
29 active in, developing countries contexts. The evidence of the impact of decarbonisation policy
30 instruments applied to developing countries or SIDS is limited. Expanding the knowledge base with
31 studies with a focus on developing countries would not only allow for testing whether the theories
32 (developed by predominantly by developed-country researchers for industrialised countries) hold in
33 developing country contexts, but also yield policy insights that could help both domestic and
34 international policymakers working on climate-related technology cooperation.

35 While a growing literature has shown how technology characteristics and complexity, national context
36 and innovation capacity can influence the capacity of a country's innovation ecosystem as a result of
37 incentive and attraction policies, more research is needed to help prioritise and design policies in
38 different national contexts while filling important knowledge gaps regarding the impact of “green”
39 public procurement, lending, “green” public banking and building code policies on innovation
40 outcomes.

41 There is also a superficial understanding of the potential and actual contributions of businesses,
42 educational institutions and socially responsible programmes, particularly in developing countries, as
43 sources of innovation and early adopters of new technologies, and a notable lack of knowledge about
44 indigenous practices.

1 Besides the strong bias of literature to studies originating from and based on developed countries,
2 innovation and technology literature is also skewed to mitigation, and within mitigation to energy.
3 Literature on technology innovation for adaptation is largely missing.

4 In the area of innovation studies, data are limited on the different indicators used to assess the strength
5 of the innovation system, even for energy, including global figures on R&D and demonstration
6 spending, also for developing countries, and their effectiveness. There is also a lack of a comprehensive
7 framework and detailed data to assess the strengths of low-emission innovation systems, including
8 interactions among actors, innovation policy implementation, and strength of institutions.

9 Another gap in knowledge remains between the results from energy-climate-economy models and those
10 emerging from systems transition and sustainability transition approaches, empirical case studies, and
11 the innovation system literature. If this gap is filled, the understanding of the feasibility of
12 decarbonisation pathways in light of the many non-technical barriers to technology deployment and
13 diffusion could be improved.

14 In the field of policy instruments, existing evaluations provide insufficient evidence to assess the impact
15 of decarbonisation policy instruments on innovation, as these evaluations mainly focus on
16 environmental or technological effects. The potential positive or negative role of domestic IPR policy
17 in technology transfer to least developed countries remains unclear as the literature does not show
18 agreement. Moreover, gaps remain in impact evaluations of sub-national green industrial policies,
19 which are of growing importance. The interaction between subnational and national decarbonisation
20 policies to advance innovation would also benefit from further research, particularly in developing
21 countries.

22 The understanding of the role of digitalisation in decarbonisation pathways is lacking and needs to be
23 studied from several angles. Existing studies do not sufficiently take into account knowledge on the
24 energy impact of digital technologies, in particular the increase in energy demand by digital devices,
25 and the increase in energy efficiency. They would benefit from being technology/sector/country-
26 specific.

27 The way in which digitalisation will influence the framework conditions under which decarbonisation
28 will occur, the socio-economic and behavioural barriers influencing the diffusion of technologies in the
29 long-term scenarios and the relationship with society and its effects need to be further explored.

30 Given the implications of the digital revolution for sustainability, a better characterisation of governance
31 aspects would increase understanding of the implications and possibilities of digitalisation and other
32 GPTs for policymakers.

33 Relatedly, research (both theoretical and empirical) on the impacts of imitation, or adaptation of new
34 technological solutions invented in one region and used in other regions, could fill knowledge gaps, in
35 order to accelerate the diffusion of climate-related technologies, while taking care not to reduce the
36 incentive for inventors to invest in the search for new solutions.

37 Lastly, an independent assessment about the compliance of the Paris Agreement with regard to
38 technology and capacity building as means of implementation is starting under the Enhanced
39 Transparency Framework for action and support, where a methodology of monitoring, reporting and
40 verification are being developed. There is also a lack of analysis of the full landscape of international
41 cooperation, of what is needed to meet the objectives of the UNFCCC and the Paris Agreement, and of
42 its effectiveness.

43

1 **Frequently Asked Questions (FAQs)**

2 **FAQ 16.1 Will innovation and technological changes be enough to meet the Paris Agreement** 3 **objectives?**

4 The Paris Agreement stressed the importance of development and transfer of technologies to improve
5 resilience to climate change and to reduce greenhouse gas emissions. However, innovation and even
6 fast technological change will not be enough to achieve Paris Agreement mitigation objectives. Other
7 changes are necessary across the production and consumption system and the society in general,
8 including behavioural changes.

9 Technological changes never happen in a vacuum, they are always accompanied by, for instance, people
10 changing habits, companies changing value chains, or banks changing risk profiles. Therefore,
11 technological changes driven by holistic approaches can contribute to accelerate and spread those
12 changes towards the achievement of climate and sustainable development goals.

13 In innovation studies, such systemic approaches are said to strengthen the functions of technological or
14 national innovation systems, so that climate-friendly technologies can flourish. Innovation policies can
15 help respond to local priorities and prevent unintended and undesirable consequences of technological
16 change, such as unequal access to new technologies across countries and between income groups,
17 environmental degradation and negative effects on employment.

18

19 **FAQ 16.2 What can be done to promote innovation for climate change and the widespread** 20 **diffusion of low-emission and climate-resilient technology?**

21 The speed and success of innovation processes could be enhanced with the involvement of a wider
22 range of actors from the industry, research and financial communities working in partnerships at
23 national, regional and international levels. Public policies play a critical role to bring together these
24 different actors and create the necessary enabling conditions, including financial support through
25 different instruments as well as institutional and human capacities.

26 The increasing complexity of technologies requires cooperation if their widespread diffusion is to be
27 achieved. Cooperation includes the necessary knowledge flow between within and between countries
28 and regions. This knowledge flow can take the form of exchanging experiences, ideas, skills, practices,
29 among others.

30

31 **FAQ 16.3 What is the role of international technology cooperation in addressing climate change?**

32 Technologies that are currently known but not yet widely used need to be spread around the world, and
33 adapted to local preferences and conditions. Innovation capabilities are required not only to adapt new
34 technologies for local use but also to create new markets and business models. International technology
35 cooperation can serve that purpose.

36 In fact, evidence shows that international cooperation on technology development and transfer can help
37 developing countries to achieve their climate goals more effectively, and if this is done properly can
38 also help addressing other sustainable development goals. Many initiatives exist both regionally and
39 globally to help countries in achieving technology development and transfer through partnerships and
40 research collaboration that include developed and developing countries, with a key role for
41 technological institutions and universities. Enhancing current activities would help an effective, long-
42 term global response to climate change, while promoting sustainable development.

1 Globalization of production and supply of goods and services, including innovation and new
2 technologies, may open up opportunities for developing countries to advance technology diffusion;
3 however, so far not all countries have benefited from the globalisation of innovation due to different
4 barriers such as access to finance and technical capabilities. These asymmetries between countries in
5 the globalization process can also lead to dependencies on foreign knowledge and providers.

6 Not all technology cooperation directly results in mitigation outcomes. Overall, technology transfer
7 broadly has focused on enhancing climate technology absorption and deployment in developing
8 countries as well as RD&D and knowledge spill-overs.

9 Paris Agreement also reflects this view by noting that countries shall strengthen cooperative action on
10 technology development and transfer regarding two main aspects: 1) promoting collaborative
11 approaches to research and development and 2) facilitating access to technology to developing country
12 Parties.

1 **Executive summary**

2
3 **Accelerating climate actions and progress towards a just transition is essential to reducing climate risks and addressing sustainable development priorities, including water, food and human security (*robust evidence, high agreement*).** Accelerating action in the context of sustainable development involves not only expediting the pace of change (speed) but also addressing the underlying drivers of vulnerability and high emissions (quality and depth of change) and enabling diverse communities, sectors, stakeholders, regions and cultures (scale and breadth of change) to participate in just, equitable and inclusive processes that improve the health and well-being of people and the planet. Looking at climate change from a justice perspective means placing the emphasis on a) the protection of vulnerable populations and low income countries from the impacts of climate change, b) mitigating the effects of the transformations, and c) ensuring an equitable decarbonized world {17.1.1}.

13
14 **While transition pathways will vary across countries, they are likely to be challenging in many contexts. (*robust evidence, high agreement*).** Climate change is the result of decades of unsustainable production and consumption patterns (for example energy production and land-use), as well as governance arrangements and political economic institutions that lock in resource-intensive development patterns (*robust evidence, high agreement*). Reframing development objectives and shifting development pathways towards sustainability can help transform these patterns and practices, allowing space for transitions to transform unsustainable systems (*medium evidence, high agreement*). {17.1.1.2}.

22
23 **Sustainable development can enhance sectoral integration and social inclusion (*robust evidence, high agreement*).** Inclusion merits attention because equity within and across countries is critical to transitions that are not simply rapid but also sustainable and just. Resource shortages, social divisions, inequitable distributions of wealth, poor infrastructure and limited access to advanced technologies can constrain the options and capacities for developing countries to achieve sustainable and just transitions (*medium evidence, high agreement*) {17.1.1.2}.

29
30 **Concrete actions aligning sustainable development and climate mitigation and partnerships can support transitions. Strengthening different stakeholders' "response capacities" to mitigate and adapt to a changing climate will be critical for a sustainable transition (*robust evidence, high agreement*).** Response capacities can be increased by means of alignment across multiple stakeholders at different levels of decision-making. This alignment will also help achieve synergies and manage trade-offs between climate and sectoral policies by breaking down sectoral silos and overcoming the multiple barriers that prevent transitions from gaining traction and gathering momentum (*medium evidence, high agreement*) {17.1.1.1}.

38
39 **Economics, psychology, governance and systems research have pointed to a range of factors that influence the speed, scale and quality of transitions (*robust evidence, high agreement*).** Views nonetheless differ on how much market-correcting policies, shift preferences (economics) and shifts in individual and collective mindsets (psychology) and multi-level governance arrangements and inclusive political institutions (governance) contribute to system transitions (*medium evidence, high agreement*) {17.2}.

45
46 **While economics, psychology, governance and systems thinking emphasize different enablers of transitions, they often share a view that strengthening synergies and avoiding trade-offs between climate and sustainable development priorities can overcome barriers to transitions (*medium evidence, high agreement*).** A growing body of research and evidence can show which factors in the views from economics, psychology, governance and systems affect how interrelationships are managed

1 between climate, mitigation policies and sustainable development. Greater integration between studies
2 based on different methodological approaches can show how to construct an enabling environment that
3 increases the feasibility and sustainability of transitions {17.2, 17.3 and 17.4}.

4
5 **Short- and long-term studies of transformations using macroeconomic models and integrated**
6 **assessment models (IAMs) have identified synergies and trade-offs of mitigation options in the**
7 **context of development pathways that align sustainable development and climate change (*robust***
8 ***evidence, high agreement*).** IAMs often look at climate change mitigation and SDGs in an aggregate
9 manner: supplementing this aggregate view with detail-rich studies involving SDGs can build support
10 for transitions within and across countries (*medium evidence, medium agreement*). {17.3.2}.

11
12 **The impacts of climate-change mitigation and adaptation responses, are highly context-specific**
13 **and scale-dependent. There are synergies and trade-offs between adaptation and mitigation as**
14 **well as synergies and trade-offs with sustainable development(*robust evidence, high agreement*).**
15 A strong link exists between sustainable development, vulnerability and climate risks, as limited
16 economic, social and institutional resources often result in low adaptive capacities and high
17 vulnerability, especially in developing countries. Resource limitations in these countries can similarly
18 weaken the capacity for climate mitigation and adaptation. The move towards climate-resilient societies
19 requires transformational or deep systemic change. This has important implications countries'
20 sustainable development pathways (*medium evidence, high agreement*) {17.3.3.6}.

21
22 **Sectoral mitigation options present synergies with the SDGs, but there are also trade-offs, which**
23 **can become barriers to implementation. Such trade-offs are particularly identified in relation to**
24 **the use of land for bioenergy crops, water and food access, and competition for land between**
25 **forest or food production (*robust evidence, high agreement*).** Many industrial mitigation options, like
26 efficiency improvements, waste management and the circular economy, have synergies with the SDGs
27 relating to access to food, water and energy (*robust evidence, high agreement*). The promotion of
28 renewable energy in some industrial sectors, can imply stranded energy supply investments, which need
29 to be taken into consideration (*medium evidence, medium agreement*). The Agriculture, Forestry, and
30 Other Land Uses (AFOLU) sector offers many low-cost mitigation options, but actions aimed at
31 producing bioenergy, extending food access and protecting biodiversity can also create trade-offs
32 between different land-uses (*robust evidence, high agreement*). Some options can help to minimize
33 these trade-offs, for example, integrated land management, cross-sectoral policies and efficiency
34 improvements. Lifestyle changes, including dietary changes and reduced food waste, have several
35 synergies with climate mitigation and the SDGs (*medium evidence, medium agreement*). Cross-sectoral
36 policies are important in avoiding trade-offs, to ensure that synergies between mitigation and SDGs are
37 captured, and to ensure local people are involved in the development of new products, as well as
38 production and consumption practices. There can be many synergies in urban areas between mitigation
39 policies and the SDGs, but capturing these depends on the overall planning of urban structures and on
40 local integrated policies, where, for example, affordable housing and spatial planning as a climate
41 mitigation measure are combined with walkable urban areas, green electrification and clean renewable
42 energy. Such integrated options can also reduce the pressures on agricultural land by reducing urban
43 growth, thus improving food security. Access to green electricity can also support quality education
44 (*medium evidence, medium agreement*). {17.3.3, 17.3.3.1, 17.3.3.3}.

45
46 **Digitalization could facilitate a fast transition to sustainable development and low-emission**
47 **pathways by contributing to efficiency improvements, cross-sectoral coordination and a circular**
48 **economy with new IT services and decreasing resource use (*low evidence, medium agreement*).**
49 Several synergies with SDGs could emerge in terms of energy, food and water access, health and
50 education, as well as trade-offs, for example, in relation to reduced employment, increasing energy

1 demand and increasing demand for services, all implying increased GHG emissions. However,
2 developing countries with limited internet access and poor infrastructure could be excluded from the
3 benefits of digitalization (*medium evidence, medium agreement*). {17.3.3}.

4
5 **Actions aligning sustainable development and climate mitigation and partnerships can support**
6 **transitions. Strengthening different stakeholders’ “response capacities” to mitigate and adapt to**
7 **a changing climate will be critical for a sustainable transition (*robust evidence, high agreement*).**
8 Response capacities can be increased by means of alignment across multiple stakeholders at different
9 levels of decision-making. This alignment will also help achieve synergies and manage trade-offs
10 between climate and sectoral policies by breaking down sectoral silos and overcoming the multiple
11 barriers that prevent transitions from gaining traction and gathering momentum (*medium evidence, high*
12 *agreement*) {17.1.1.1}.

13
14 **The landscape of transitions to sustainable development is changing rapidly, with multiple**
15 **transitions already underway. This creates the room to manage these transitions in ways that**
16 **prioritise the needs for workers in vulnerable sectors (land, energy) to secure their jobs and**
17 **maintain secure and healthy lifestyles, especially as the risks multiply for those exposed to heavy**
18 **industrial jobs and associated outcomes (*medium evidence, high agreement*). {17.3.2.3}. A just**
19 transition incorporates key principles, such as respect and dignity for vulnerable groups, the creation of
20 decent jobs, social protection, employment rights, fairness in energy access and use, and social dialogue
21 and democratic consultation with the relevant stakeholders, while coping with the effects of asset-
22 stranding and the transition to green and clean economies (*medium evidence, medium agreement*). The
23 economic implications of the transition will be felt especially strongly by developing countries, with
24 high dependence on hydrocarbon products for revenue streams, as they will be exposed to reduced fiscal
25 incomes given a low demand for oil and consequent fall in oil prices (*limited evidence, medium*
26 *agreement*). {17.3.2}.

27
28 **Countries with assets that are at risk becoming stranded may lack the relevant resources,**
29 **knowledge, autonomy or agency to reorientate, or to decide on the speed, scale and quality of the**
30 **transition (*limited evidence, medium agreement*). The urgency of mitigation might overshadow some**
31 of the other priorities related to the transition, like climate change adaptation and its inherent
32 vulnerabilities. Consequently, the transition imperative could reduce the scope and autonomy for local
33 priority-setting and could ignore the additional risks in countries with a low capacity to adapt. A just
34 transition will depend on local contexts, regional priorities, the starting points of different countries in
35 the transition and the speed at which they want to travel. Both mitigation and adaptation warrant urgent
36 and prompt action given current and continuing greenhouse gas emissions and associated negative
37 impacts on humanity and ecosystems. (*limited evidence, medium agreement*). {17.3.2}.

38
39 **A wide range of factors have been found to enable sustainability transitions, ranging from**
40 **technological innovations to shifts in markets, and from policies and governance arrangements**
41 **to shifts in belief systems and market forces (*robust evidence, high agreement*). Many of these**
42 factors come together in a co-evolutionary process that has unfolded globally, internationally and
43 locally over several decades (*low evidence, high agreement*). Those same conditions that may serve to
44 impede the transition (i.e., organizational structure, behaviour, technological lock-in) can also ‘flip’ to
45 enable both it and the framing of sustainable development policies to create a stronger basis and policy
46 support (*robust evidence, high agreement*). It is important to note that strong shocks to these systems,
47 including accelerating climate change impacts, economic crises and political changes, may provide
48 crucial openings for accelerated transitions to sustainable systems. For example, re-building more

1 sustainably after an extreme event, or renewed public debate about the drivers of social and economic
2 vulnerability to multiple stressors (*medium evidence, medium agreement*) {17.4}.

3
4 **Sustainable development and deep decarbonization will involve people and communities being**
5 **connected through various means, including globally via the internet and digital technologies, in**
6 **ways that prompt shifts in thinking and behaviour consistent with climate change goals (*medium***
7 ***evidence, medium agreement*). Individuals and organizations like institutional entrepreneurs can**
8 **function to build transformative capacity through collective action (*robust evidence, high agreement*),**
9 **but private-sector entrepreneurs can also play an important role in fostering and accelerating the**
10 **transitions to sustainable development (*robust evidence, medium agreement*). Ultimately, the adoption**
11 **of coordinated, multi-sectoral policies targeting new and rapid innovation can help national economies**
12 **take advantage of widespread decarbonization. Green industrial policies that focus on building domestic**
13 **supply chains and capacities can help states prepare for the influx of renewable, CDR-methods, or**
14 **mechanisms for carbon capture and storage (*medium evidence, medium agreement*){17.4.2}.**

15
16 **Accelerating the transition to sustainability will be enabled by explicit consideration being given**
17 **to the principles of justice, equality and fairness. Interventions to promote sustainability**
18 **transitions that account for local context (including unequal access to resources, capacity and**
19 **technology) in the development process are necessary but not sufficient in creating a just**
20 **transition (*low evidence, high agreement*). {17.4.6}**

17.1 Introduction

This chapter focuses on the opportunities and challenges for “accelerating the transition in the context of sustainable development.” The chapter suggests that accelerating transitions in the context of sustainable development requires more than concentrating on speed. Rather, it involves expediting the pace of change (speed) while also removing the underlying drivers of vulnerability and high emissions (quality and depth) and aligning the interests of different communities, regions, sectors, stakeholders and cultures (scale and breadth). One key to enabling deep and broad transitions is integrating the views of different government agencies, businesses and non-governmental organizations (NGOs) in transition processes. Another critical driver of deep and broad transitions is engaging and empowering workers, youth, women, the poor, minorities and marginalized stakeholders in just, equitable and inclusive processes. The result of such processes will be the transformation of large-scale socioeconomic systems to restore the health and well-being of the planet and the people on it.

Section 17.1 begins by reviewing how climate and sustainability issues have been discussed in the Intergovernmental Process on Climate Change (IPCC), as well as international climate change and sustainable development processes at different levels. It further introduces key themes addressed in the chapter’s remaining subsections. Section 17.2 provides an overview of how key theories understand transitions and transformation, and notes a shared concern over leveraging synergies and managing trade-offs between climate change and sustainable development across different disciplines. Section 17.3 provides an assessment of the mitigation options that can help achieve these synergies and avoid trade-offs. 17.4 pulls together the theoretical and empirical aspects by detailing the essential elements of an enabling environment that helps drive forward transitions that are quick, deep, broad and, ultimately, sustainable.

17.1.1 Integrating Climate Change and Sustainable Development in International Assessments

Climate change not only poses a profound challenge to sustainable development, it is inexorably linked to it. From the early stages of the IPCC assessment process, this challenge and the inherent link between climate change and sustainable development have been well recognized. For example, the First Assessment Report (FAR) highlighted the relevance of sustainable development for climate policy. The Second Assessment Report (SAR) went further to include equity issues in its presentation of sustainable development. The Third Assessment Report (TAR) (Banuri et al. 2001) made the link even stronger, noting that “parties have a right to and should promote sustainable development” (as stated in the text of the UNFCCC 2015 (Article 3.4)), and offering an early review of studies integrating sustainable development and climate change. The Fourth Assessment Report (AR4) (Sathaye et al. 2007) added an additional perspective to these interconnections, acknowledging the existence of a two-way relationship between sustainable development and climate change.

The Fifth Assessment Report (AR5) (Denton et al. 2014; Fleurbaey et al. 2014) and the Special Report on Global Warming of 1.5°C (IPCC 2018; Roy et al. 2018a) have arguably made the strongest links between climate and sustainable development to date. One of the key messages of AR5 was that the implementation of climate mitigation and adaptation actions could help promote sustainable development, and it emphasized the need for transformational changes in this regard. AR5 also concluded that the link between climate change and sustainable development is cross-cutting and complex, and that thus the impacts of climate change are threatening the efforts being made to achieve sustainable development. The IPCC special report on Global Warming of 1.5°C helped systematize these links by mapping the synergies and trade-offs between selected SDG indicators and climate mitigation (IPCC 2018; Roy et al. 2018b) (see also sect. 17.3).

1 Despite the clear links between sustainable development and climate change being recognised from the
2 early stages of the IPCC, climate change has often been portrayed as an environmental problem to be
3 addressed chiefly by environmental ministries (Brown et al. 2007; Munasinghe 2007; Swart and Raes
4 2007). However, this perception has evolved over time. It is now increasingly common to see
5 governments and other actors understand the wider ramifications of a changing climate for sustainable
6 development. In a growing number of studies, work on climate policies and just transitions towards
7 sustainable development are framed as going hand in hand (Fuso Nerini et al. 2019; Dugarova and
8 Gülasan 2017; Sanchez Rodriguez et al. 2018; Schramade 2017; Zhenmin and Espinosa 2019).
9

10 **17.1.2 Integrating Climate Change and Sustainable Development in International** 11 **Policymaking Processes**

12 Among the reasons for the growing realization of these interdependencies are milestones in
13 international climate and sustainable development processes. As outlined in Chapter 14, the year 2015
14 was a turning point due to two agreements: 1) the Paris Agreement; and 2) the 2030 Agenda on
15 Sustainable Development and its seventeen Sustainable Development Goals (SDGs) (Farzaneh et al.
16 2021).
17

18 Following a long history of references to sustainable development in the UNFCCC and related
19 agreements, the Paris Agreement helped to strengthen the links between climate and sustainable
20 development by emphasizing that sustainability is related to its objectives (Sindico 2016; UNFCCC
21 2016). One of the ways that it helped tighten this link is by institutionalizing bottom-up pledges and the
22 review architecture. Toward this end, the Paris Agreement instituted nationally determined
23 contributions (NDCs) as vehicles through which countries make pledges and demonstrate their
24 commitment to climate action. Although there was no clear guidance on what should be included in the
25 NDCs, some of the requirements were elaborated in the Paris Rule Book (see above, Chapter 14). Some
26 of the submitted NDCs included only mitigation efforts, but others set out mitigation and adaptation
27 goals aligning NDC commitments to national planning processes, while yet others mentioned links with
28 the SDGs.
29

30 Another way that the Paris Agreement and the NDCs could strengthen their links to sustainable
31 development is to update country-specific climate pledges. Countries are free to choose their targets
32 and the means and instruments with which to implement them. A core feature of the NDCs was that
33 countries submit NDCs every five years, giving them an opportunity to assess themselves relative to
34 other countries, raise their ambitions and learn from their peers. Moreover, it was emphasized that
35 countries should not “backslide” in subsequent NDCs, thus ensuring that countries should always be
36 forward-looking in respect of increasing their ambitions to deliver the Paris Goals. Höhne et al. (2017)
37 found that, in developing countries especially, the NDC preparation process has improved national
38 climate policy-making.
39

40 Despite some favourable reviews, several assessments of specific countries’ NDCs (Andries et al. 2017;
41 Rogelj et al. 2016; Vandyck et al. 2016) have assessed that those submitted for 2020-2030 are
42 insufficient for delivering on the Paris goals. Updated and/or new NDCs were therefore submitted by
43 end of 2020. However, an assessment of those NDCs revealed that the level of ambition was
44 significantly lower than the goals of the Paris Agreement (UNFCCO 2020; see also this Chapter). One
45 of the urgent calls in Paris was to assess the impacts and efforts that need to be undertaken to keep
46 global warming well below 2°C in relation to pre-industrial levels and evaluate related global
47 greenhouse-gas emission pathways (UNFCCC 2015). Although the initial NDCs fell short of these
48 goals, the idea was that NDCs would be living documents that could ratchet up climate action and
49 ambition.
50

51 Countries have also started to take actions on the SDGs themselves (Antwi-Agyei et al. 2018a;
52 UNDESA 2016, 2017, 2018). The SDGs were perceived as a novel approach to development and as
53 establishing a universal agenda for the transformation of development patterns and socioeconomic
54 systems. At their core, the SDGs hold that building an integrated framework for action necessitates

1 addressing the economic, social and environmental dimensions of sustainable development in an
2 integrated manner (Biermann et al. 2017; Kanie and Biermann 2017). The SDGs take multiple elements
3 of development into account in aiming to offer coherent, well-integrated, overarching approaches to a
4 range of sustainability challenges, including climate change.

5
6 One way a link is made between climate and the SDGs is through Voluntary National Reviews (VNRs).
7 Paralleling the bottom-up orientation of the Paris Agreement and the NDCs, every year approximately
8 forty countries voluntarily share their VNRs with the international community at the High-Level
9 Political Forum (HLPF). Even more flexible than the NDCs, the VNRs can include content such as a
10 summary of key policies and measures that are intended to achieve the SDGs, a list of the means of
11 implementation that support the SDGs, and related challenges and needs. The VNRs also often cover
12 SDG 13 (on climate change) as well as many other issues connected with climate change. Even with
13 these links, implementation of the SDGs should be mentioned as part of national development processes
14 reflecting different countries' different priorities, visions and plans (Hanson and Ptoplampu 2018;
15 Marcotullio et al. 2018; OECD 2016; Ptoplampu et al. 2017; Srikanth 2018).

16
17 Yet another way that the 2030 Agenda for Sustainable Development underlines the importance of
18 capturing synergies is its calls for policy coherence (goals 17 and 14). Policy coherence and integration
19 between sectors are two of the most critical factors in breaking down the silo mode of working of
20 different sectors. Working across climate and other sustainability agendas is essential to coherence.

21
22 A final way that the sustainability and climate agendas have been linked is through vertical integration.
23 Following a similar trend that appeared with Agenda 21, for which many cities adopted local plans, a
24 growing number of cities have introduced Voluntary Local Reviews. The VLRs resemble the VNRs,
25 but place the emphasis on local actions and needs regarding the SDGs (and some links to climate
26 change) (Ortiz-Moya et al. 2021). The 2019 SDG Report shows that 150 countries have developed
27 national urban plans, almost half of them also being in the implementation phase (United Nations
28 General Assembly 2019).

29 30 **17.1.3 Integrating Climate Change and Sustainable Development in Other Policymaking** 31 **Processes**

32 Other non-UN-led initiatives involving international organizations or clusters of countries have also
33 helped to raise the issue of sustainable development as a framework for mitigation. The OECD, for
34 instance, assesses different types of investments and economic activities with reference to their
35 significance for environmental sustainability (OECD 2020), while G20 countries have drawn up action
36 agendas with sustainable development at the (UToronto 2016). Meanwhile, the Petersberg Climate
37 Dialogue, a political movement convened by major country-group representatives launched in 2010 by
38 the German government, has also called for sustainability to be an intrinsic part of the transition
39 (UNFCCO 2020; BMU 2018).

40 Due in part to the shifting orientation of these international processes, there is growing evidence of
41 action on climate change and sustainable development at other levels of decision-making. National
42 policies often aim to implement climate change policies in the context of sustainable development
43 (Chimhowu et al. 2019; Chirambo 2018; ECLAC 2017; Fuseini and Kemp 2015; Galli et al. 2018;
44 Haywood et al. 2019; Ministry of Environment of Jordan 2016; McKenzie and Abdulkadri 2018;
45 UNDESA 2016, 2017, 2018; UN Women 2017). Some countries are adjusting their existing policies to
46 build on themes familiar to sustainable development (Lucas et al. 2016), including renewable energy
47 and energy efficiency (Fastenrath and Braun 2018; Kousksou et al. 2015), urban planning (Gorissen et
48 al. 2018; Loorbach et al. 2016; Mendizabal et al. 2018), health systems (Pencheon 2018; Roschnik et
49 al. 2017) and agricultural systems (Lipper and Zilberman 2018; Shaw and Roberts 2017). Cross-cutting
50 and integrated approaches, such as the circular economy, have also been gaining traction in some
51 European countries (EESC 2015) and G20 countries (Noura et al. 2020). Many of these efforts have
52 also extended up to the regional and down to the local level (Gorissen et al. 2018; Hess 2014; Shaw and
53 Roberts 2017).

1
2 There has also been a shift to actors outside government aligning climate with sustainable development.
3 An assessment by Hoyer (2020) found that collective action against climate change by businesses,
4 governments and civil society, reinforced through partnerships and coalitions across departments,
5 industries and supply chains, can deliver significant development impacts. In order for this diverse
6 collection of stakeholders to take action, a fundamental paradigm shift is needed from a linear model of
7 knowledge-generation to an interdisciplinary model that co-produces knowledge (Liu et al. 2019). In
8 fact, some have argued that accelerating just transitions for purposes of sustainable development
9 requires the involvement of several actors, institutions and disciplines (Delina and Sovacool 2018). Not
10 only do these roles need to be discussed more thoroughly (Kern and Rogge 2016; den Elzen et al. 2019),
11 but it is also important to survey different views on transitions and transformations. A variety of theories
12 that are useful for explaining the causes and constraints regarding transitions are examined in Section
13 17.2.
14
15

16 **17.2 Accelerating Transitions in the Context of Sustainable Development:** 17 **Definitions and Theories**

18 This section focuses on how different theoretical frameworks can help us understand and explain what
19 is meant by accelerating transitions in the context of sustainable development. As suggested in sect.
20 17.1, the reference to “*in the context of sustainable development*” suggests that sustainable transitions
21 require more than speed, also necessitating removing the underlying drivers of vulnerability and high
22 emissions (quality and depth of transitions) while also aligning the interests of different individuals,
23 communities, sectors, stakeholders and cultures (scale and breadth of transitions).
24

25 The outcome of sustainable transitions is a sustainable *transformation*. While transitions involve
26 *processes that shift development pathways and reorient energy, transport, urban and other subsystems*
27 (Loorbach et al. 2017; Chapter 16), transformation is the resulting *fundamental reorganization of large-*
28 *scale socioeconomic systems* (Hölscher et al. 2018). Such a fundamental reorganization often requires
29 dynamic multi-stage transition processes that change everything from public policies and prevailing
30 technologies to individual lifestyles, and social norms to governance arrangements and institutions of
31 political economy. This set of factors can lock in development pathways and prevent transitions from
32 gathering the momentum needed for transformations. Chapter 16 (above) provides an overview of the
33 multistage transition dynamics involved in moving from experimentation to commercialization to
34 integration to stabilization. That overview describes how transitions can break through lock-ins and
35 result in a transformation.
36

37 While there may be a relatively consistent set of transition dynamics for all countries, pathways are
38 likely to vary across and even within countries. This variation is due to different development levels,
39 starting points, capacities, agencies, geographies, power dynamics, political economies, ecosystems and
40 other contextual factors. Given the diversity of contributing factors, a sustainable transition is likely to
41 be a complex and multi-faceted process which cannot be reduced to a single dimension (Köhler et al.
42 2019). Even with this multi-dimensionality, transition processes are likely to gain speed and become
43 more sustainable as decision-makers adopt targeted policies and other interventions. Many disciplines
44 have reflected on the roles of and relative influence on the policies and interventions that can drive
45 transitions. The following discussion describes this diversity of views with a survey of how prominent
46 lines of economic, psychological, institutional and systems thinking explain transitions. Though these
47 disciplines differ greatly, they often stress that leveraging synergies and managing trade-offs between
48 climate change and sustainable development can help advance a transition.
49

50 **17.2.1 Economics**

51 This section concentrates on economic explanations for transitions. At the core of many of these
52 explanations is the assumption that economic development can deliver multiple economic, social and

1 environmental benefits. Many modern economic systems may nonetheless struggle to deliver these
2 benefits due to major disruptions and shocks such as climate change (Heal 2020). One way to limit
3 disruptions to free markets are targeted interventions in free markets such as taxes or regulation. These
4 targeted interventions motivate firms and other entities to internalize GHGs and other pollutants,
5 potentially paving the way for a sustainable transition (Arrow et al. 2004; Chichilnisky and Heal 1998).

6
7 A related line of thought common to economic explanations involves the principles of “weak
8 sustainability”. These principles suggest that the substitution of exhaustible resources is, to some extent,
9 feasible (Arrow et al. 2004). One way to capitalize on this substitution is to target investments at
10 technological change, green growth, and research and development. Targeted investments in the form
11 of subsidies can encourage the substitution of exhaustible by non-exhaustible resources. To illustrate
12 with a concrete example, investments in renewable energy can not only mitigate climate change but
13 also offset the use of exhaustible fossil fuels and boost energy security (Heal 2020). It is nonetheless
14 important to note that the principles of “weak sustainability” contrasts with “strong sustainability” or
15 “integrated sustainability” principles. These stronger principles suggest that constraints on resources
16 restrict such substitutions (Rockström et al. 2009). These constraints merit attention because some
17 scarce non-substitutable forms of natural capital can be exhausted (Bateman and Mace 2020). There is
18 hence a need to capitalize on possible synergies such as those with other development priorities and
19 trade-offs, for example, the exhaustion of non-substitutable resources. Capturing these synergies and
20 managing these trade-offs is consistent with sustainable development, a state where the needs of the
21 present generation do not compromise the ability of future generations to meet their own needs
22 (Bruntland, WCED 1987).

23
24 As suggested above, aligning climate investments with other sustainable development objectives is
25 critical to a transition. In order to support better investments in sustainable development, financing
26 schemes, including environmental, social and governance (ESG) disclosure schemes and the Task Force
27 on Climate-Related Financial Disclosures (TCFD), can play important roles (Executive Summary in
28 Chapter 15). After COVID-19, economic recovery packages have increased government-led
29 investments (Section 1.3.3 in Chapter 1), which could potentially be aligned with sustainable
30 development. Technological change and innovation are considered key drivers of economic growth and
31 of many aspects of social progress (Section 16.1 in Chapter 16), but if technological innovation policies
32 are coordinated with the shift to sustainable development pathways, then the economic benefits of
33 technological change could come at the cost of increasing climate risks (Chapter 16, Gossart 2015)
34 Chapter 16, 16:1; Alarcón and Vos 2015). The environmental impacts of social and economic activities,
35 including emissions of GHGs, are greatly influenced by the rate and direction of technological changes.
36 Innovation and technological transformations present trade-offs that create externalities and rebound
37 effects. This suggests that a sustainable future for people and nature requires rapid, radical and
38 transformative societal change by integrating the technical, governance, financial and societal aspects
39 (Chapter 16, 16.1; Pörtner et al. 2021).

40
41 One area that is pertinent to transitions and has received considerable attention in economic modelling
42 involving climate change is innovation. In particular, some studies have shown how low-cost
43 innovations and improvements in end-use technologies have significant potential for emissions
44 reductions as well as sustainable development (Wilson et al. 2019). Currently information technologies
45 are improving rapidly, and IoT, AI and Big Data can all contribute to other development needs. This is
46 often the case in end-use sectors, as the benefits accrue directly to the individuals who use the new
47 innovations. The achievement and widespread deployment of fully autonomous cars, for example, will
48 bring about broader car- and ride-sharing with negative or low additional costs compared to more
49 conventional approaches to car ownership, with their typically very low load factors. (Grubler et al.
50 2018) estimate that the low energy demand (LED) scenario which assumes information technology
51 innovations and induced social changes, including a sharing economy, have considerable potential for
52 harmonizing the multiple achievements of SDGs with low marginal abatement costs compared with
53 other scenarios (IPCC 2018).

1 It is nonetheless important to highlight a caveat to the above logic on innovation. Whether a
2 technological innovation is wholly sustainable or not becomes less clear when considering its effects
3 on the wider economy. To illustrate, some models predict that CO₂ marginal abatement costs in the
4 power sector will be 240 and 565 USD/tCO₂ for the 2 degree and below 2 degree goals respectively
5 (IEA 2017).

6
7 In theory, if marginal abatement costs meet marginal climate damage, mitigation measures are
8 economically optimal in the long run. Yet marginal damage from climate change is notoriously
9 uncertain, and economic theories do not always reflect climate-related damage. On the other hand,
10 marginal abatement mitigation costs impose additional costs in the short term. These added costs can
11 cause productivity in capital to decline through increases in the prices of energy and products in which
12 the energies are embodied. These increased costs can restrict the ability to invest in and achieve the
13 sustainable development priorities. However, precisely the opposite can occur when innovation reduces
14 additional costs or achieves negative costs. If technological innovation leads to the accumulation of
15 capital and productivity increases due to the substitution of energy, material and labour, these are likely
16 to deliver sustainable development and climate mitigation benefits.

17 18 **17.2.2 Institutions, Governance, and Political Economy**

19 This subsection focuses on institutions, governance and the political economy. Institutional and
20 governance arrangements can influence which actors possess authority, as well as how motivated they
21 are to cooperate in transition processes that are directed at finding solutions to climate change and other
22 sustainability challenges. Often cooperation is enabled when policy frameworks or institutions align
23 climate change with the political and economic interests of national governments, cities or businesses,
24 and when institutional and governance arguments that support that alignment expand the scale of the
25 transitions. However, there may also be political and economic interests and structures that can lock in
26 unsustainable development patterns, frustrate this alignment and slow down transitions (Haas 2021;
27 Mattioli et al. 2020; Newell and Mulvaney 2013; Power 2016).

28
29 An extensive literature has examined how the international climate agreements and architecture
30 influence collaboration across countries regarding climate and sustainable development to support a
31 transition (Bradley 2005). For example, international institutions offer opportunities for governments
32 and other actors to share new perspectives on integrated solutions (Cole 2015). For some observers,
33 however, decades of difficulties in crafting a comprehensive climate-change agreement and the
34 resulting fragmented climate-policy landscape have been inimical to the collaboration needed for a
35 transition (Chapter 1 and 13; Nasiritousi and Bäckstrand 2019; van Asselt 2014). Yet others see the
36 potential for more incremental cooperation across countries, even without a single, integrated forms of
37 climate governance (Keohane and Victor 2016).

38
39 A related argument suggests that fragmentation at the global level provides opportunities for
40 cooperation at the national level (Kanie and Biermann 2017). For example, in contrast to the relatively
41 top-down Kyoto Protocol, the bottom-up pledge and review architecture of the Paris Agreement has
42 prompted national governments to integrate climate change with other sustainable development
43 priorities (Nachmany and Setzer 2018; Townshend et al. 2013). Concrete examples included
44 incorporating the SDGs into the NDCs as an international response to climate change (The Energy and
45 Resources Institute 2017) or bringing climate into sustainable development strategies and so-called
46 voluntary national reviews (VNRs) as part of the SDG and 2030 Agenda process (Elder and King 2018;
47 Elder and Bartalini 2019).

48
49 Another branch of institutional research is concerned with the interactions between multiple levels of
50 governance. In this multi-level governance perspective, cities and other subnational governments often
51 lead transitions by devising innovative solutions to challenged to climate and local energy, transport,
52 the environment, resilience and other forms of sustainability (Bellinson and Chu 2019; Doll and Puppim
53 De Oliveira 2017; Geels 2011; Koehn 2008; Rabe 2007; van der Heijden et al. 2019). A complementary
54 perspective suggests that national governments can help scale up transitions by allocating resources and

1 can provide the technical support that can spread innovative solutions (Bowman et al. 2017; Corfee-
2 Morlot et al. 2009; Gordon 2015). Such support has become increasingly important during the
3 pandemic, as national government transfer funds for investments in climate-friendly infrastructure,
4 transport systems and energy systems. This line of thinking is supported by calls to strengthen vertical
5 and horizontal integration within and across government agencies and stakeholders in ways that can
6 enhance policy coherence (Amanuma et al. 2018; OECD 2018, 2019). The incoherence or misalignment
7 between national and local fiscal institutions and policies can restrict the ability of local governments
8 to secure resources for climate-friendly investments. Such investments are particularly likely to flow,
9 as more local governments have adopted net zero targets, climate emergency declarations and action
10 plans that can stimulate innovations (Davidson et al. 2020). Others have seen greater potential for
11 collaboration and innovation, with more multi-centred or polycentric forms of governance that lead to
12 the formulation and dissemination of transformative solutions to climate and other environmental
13 challenges (Ostrom 2008). Though much of the above governance research has focused on western
14 countries, there are some applications in other regions and countries such as China (Gu et al. 2020).

15
16 Yet another set of channels facilitating integration between climate and other concerns are networks of
17 like-minded actors working across administrative borders and physical boundaries. For instance, city
18 networks such as the Global Covenant of Mayors for Climate and Energy (Covenant of Mayors 2019),
19 the World Mayors Council on Climate Change (ICLEI 2019; C40 Cities 2019) and UN-UNDRR (2019)
20 have agreed to share decision-making tools and good practices, and to sponsor ambition-raising
21 campaigns that help align climate and sustainable development concerns within and across cities
22 (Betsill and Bulkeley 2006) (see Chapter 8 and Section 17.3.3.5). This can be particularly important for
23 less capable “following” and “laggard” cities needing greater financing and other forms of support to
24 move a transition forward (Fuhr et al. 2018).

25
26 Furthermore, sub-national governments may often work together with civil-society groups to create
27 new networked forms of governance (Biermann et al. 2012). Other forms of multi-stakeholder
28 partnerships focusing on issues with strong climate synergies, such as forms of air pollution known as
29 short-lived climate pollutants (Climate and Clean Air Coalition (CCAC)) or transport (Sustainable Low
30 Carbon Transport Partnership (SLoCaT)), take their cue from global scientific communities or civic-
31 minded advocacy groups that transmit knowledge across boundaries (Keck and Sikkink 1999). There
32 is also scope for suggesting that the international climate regime serves a Global Framework for Climate
33 Action (GFCA) in helping orchestrate the multilateral climate regime and non-state and subnational
34 initiatives (Chan and Pauw 2014), though questions remain about its actual impacts on mitigation
35 (Michaelowa and Michaelowa 2017).

36
37 Policymaking institutions and networks are themselves policies. A significant literature has looked at
38 integrated policy frameworks and efforts across sectors, including climate adaptation and mitigation, as
39 drivers of transitions (Landauer et al. 2015; Favretto et al. 2018; Obersteiner et al. 2016; Steen and
40 Weaver 2017; Thornton and Comberti 2017). Policy coherence between climate and other development
41 objectives is often considered essential to sustainable development (Sovacool 2018). A similar
42 discussion about synergies and conflicts has been raised on the relationship between resilience and
43 sustainability (Marchese et al. 2018). To help achieve coherence, there have been some efforts to
44 develop suitable tools and decision-making frameworks (Scobie 2016).

45
46 A related line of reasoning has suggested that sustainable development often requires not one but a mix
47 of policy instruments to bring about the multiple policy effects needed for social and technological
48 change (Edmondson et al. 2019; Rogge and Johnstone 2017). Following these calls, some governments
49 have aimed to address climate change and sustainability jointly with coherent and integrated approaches
50 to achieving these agendas (Chimhowu et al. 2019), although for some countries (SIDS) this has proven
51 more challenging (Scobie 2016).

52
53 Though the above work tends to downplay politics and business, others suggest that political economy
54 should feature prominently in transitions. Some branches of political-economy research underline how

1 resource-intensive and fossil-fuel industries leverage their resources and positions to undermine
2 transitions (Chapter 1; Geels 2014; Jones, C.A. and Levy 2009; Moe 2014; Newell and Paterson 2010;
3 Zhao et al. 2013). These vested interests can lock in status quo policies in countries where political
4 systems offer interest groups more opportunities to veto or overturn climate- or eco-friendly proposals
5 (Madden 2014). Companies with a strong interest in earning profits and building competitiveness from
6 conventional fossil fuel-based energy systems have particularly strong incentives to capture politicians
7 and agencies (Meckling and Nahm 2018). Such strategies can be particularly powerful when combined
8 with concerns over job losses and dislocation, preventing transitions from gaining traction (Haas 2021;
9 Mattioli et al. 2020; Newell and Mulvaney 2013; Power 2016).

10
11 This suggests that politics can be an impediment to change: other studies argue instead that politics can
12 be harnessed to drive transitions forward. For example, some observers contend that building coalitions
13 around green industrial policies and sequencing reforms to reward industries in such coalitions can align
14 otherwise divergent interests and inject momentum into transitions (Meckling et al. 2015). Others see
15 the effects of political economy varying over time depending upon external market conditions. To
16 illustrate, renewable feed-in tariffs in Europe persisted for over two decades and were crucial in wind
17 and solar power technologies making the breakthrough. But once competition from China led to the
18 demise of European technology providers, and once European populations started to oppose surcharges
19 on their electricity bills, feed-in tariffs were abolished by politicians in the purely national interest
20 (Michaelowa and Michaelowa 2017).

21 22 **17.2.3 Psychology, Individual Beliefs and Social Change**

23 This subsection draws on value- and action-oriented research that employs inter- or transdisciplinary
24 methods such as transactional psychology, transformative science and similarly focused disciplines
25 (Wamsler et al. 2021). These approaches frequently encourage researchers to participate in transitions
26 that induce changes in the researcher's own beliefs while triggering wider shifts in social norms
27 (including human stewardship for the natural environment) (Adger et al. 2013; Hulme 2009; Ives et al.
28 2019; O'Brien 2018). This research also emphasizes how changes in individual beliefs could lead to
29 climate actions that contribute to more sustainable, equitable and just societies (see e.g. "the mind- &
30 paradigm shifts" (Göpel et al. 2016; Meadows 2008). They further suggest the potential for virtuous
31 cycles of individual-level and wider social changes that ultimately benefit the climate (Banks 2007;
32 Day et al. 2014; Lockhart 2011; Montuori and Donnelly 2018; Power 2016).

33
34 The starting point for this virtuous circle are inner transitions. Inner transitions occur within individuals,
35 organizations and even larger jurisdictions that alter beliefs and actions involving climate change
36 (Woiwode et al. 2021). An inner transition within an individual (see e.g., Parodi and Tamm 2018)
37 typically involves a person gaining a deepening sense of peace and a willingness to help others, as well
38 as protecting the climate and the planet (see e.g., Banks 2007; Power 2016). Inner transition can imply
39 that individuals become sympathetic to concerns that include climate issues and values connected to
40 nature. For instance, they may include a desire to become a steward of nature (Buijs et al. 2018), "live
41 according to the principles of integrated sustainability" (Schweizer-Ries 2018), "achieve the good life"
42 (see Section 1.6.2 in Chapter 1; Asara et al. 2015; Escobar 2015; Kallis 2017; Latouche 2018; Chapter
43 5) or protect the well-being of other living creatures (Section 1.6.3.1 in Chapter 1 and Chapter 5).

44
45 Examples have also been seen in relation to a similar set of inner transitions to individuals, organizations
46 and societies, which involves embracing post-development, de-growth, or non-material values that
47 challenge carbon-intensive lifestyles and development models (Kothari 2019; Neuteleers and Engelen
48 2015; Paech 2017; Sklair 2016). These shifts in values can occur when humans reconnect with nature,
49 deepen their consciousness and take responsibility for protecting the planet and its climate (Cross et al.
50 2019; Martinez-Juarez et al. 2015; Speldevinde et al. 2015). Changes in both values and beliefs may
51 also emerge through consciousness-raising processes where people cooperate in ways that would
52 protect the climate (see Section 1.6.4 in Chapter 1; Banks 2007; Hedlund-de Witt et al. 2014; Woiwode
53 and Woiwode 2019).

1 Many of the above-mentioned beliefs and values that support climate actions have spread through
2 expanding interests in conservationist world views, indigenous cultures (see e.g., Lockhart 2011) and
3 branches of neuroscience and psychology that suggest different notions of the self (Hüther 2018; Lewis
4 2016; Seligman and Csikszentmihalyi 2014). These beliefs and values can also be spread through
5 meditation, yoga or other social practices that encourage lower carbon lifestyles (Woiwode and
6 Woiwode 2019). Another channel for spreading climate concerns is sustainability culture, which is
7 premised on connecting people and communities, and has also benefited from the internet and digital
8 technologies that support these connections (see e.g., Bradbury 2015; Scharmer 2018). The spread of
9 this culture, in turn, has led to the creation of social fields that allow changes to happen (see e.g.,
10 Gillard et al. 2016) or has promoted low-carbon thinking and related behavioural changes (O'Brien
11 2018; Veciana and Ottmar 2018). Studies of social contagions may also offer insights into the
12 mechanisms that lead to the adoption of new values and related climate actions (see e.g., Iacopini et al.
13 2019). It is nonetheless worth highlighting that communication networks and other mechanisms
14 promoting the spread of interpersonal communication that can spread pro-climate views may also lead
15 to the proliferation of climate scepticism and denial (Leombruni 2015). At the same time, some studies
16 suggest that such scepticism can be countered by the generation of more credible information on climate
17 change (Samantray and Pin 2019).

18
19 One of the more direct channels through which transitions spread are climate change education and
20 action-oriented research (Fazey et al. 2018; Ives et al. 2019; Scharmer 2018; Schöpke et al. 2018;
21 Schneidewind et al. 2016). For instance, research using “social experiments” or “real world labs” has
22 helped give rise to shifts in mindsets on energy, food, transport and other systems that can benefit the
23 climate (Bernstein and Hoffmann 2018; Berkhout et al. 2010; Bulkeley et al. 2015; Hoffmann 2010).
24 In much the same way, the acquisition of transformational knowledge and transformative learning
25 (Lange 2018; O’Neil and Boyce 2018; Pomeroy and Oliver 2018; Walsh et al. 2020; Williams 2013)
26 contributes to thinking and acting that open climate-friendly development pathways (Berkhout et al.
27 2010; Lo and Castán Broto 2019; Roberts et al. 2018; Turnheim and Nykvist 2019; Section 1.7.2 in
28 Chapter 1). First-person and action research can also facilitate similar changes that bring about climate
29 actions (see e.g. Bradbury et al. 2019; Dick 2007; Hutchison and Walton 2015; Streck 2007).

30 **17.2.4 System Level Explanations**

31
32 Systems explanations help explain the dynamics of transitions toward sustainable development while
33 explicitly uncovering links between the human and natural worlds, the socio-cultural embeddedness of
34 technology, and the inertia behind high-carbon development pathways. This line of thinking often
35 envisages transitions emerging from complex systems in which many different elements interact at
36 small scales and spontaneously self-organize to produce behaviour that is unexpected, unmanaged and
37 fundamentally different from the sum of the system’s constituent parts.

38
39 Social-ecological systems theory describes the processes of exchange and interaction between human
40 and ecological systems, investigating in particular non-linear feedback occurring across different scales
41 (Folke 2006; Holling 2001). This approach has informed subsequent theoretical and empirical
42 developments, including the ‘planetary boundaries’ approach (Rockström et al. 2009),
43 conceptualizations of vulnerability and adaptive capacity (Hinkel 2011; Pelling 2010) and more recent
44 explorations of urban resilience (Romero-Lankao et al. 2016) and regenerative sustainability (Clayton
45 and Radcliffe 2018; Robinson and Cole 2015). Employing a systems lens to address the ‘root causes’
46 of unsustainable development pathways (such as dysfunctional social or economic arrangements) rather
47 than the ‘symptoms’ (dwelling quality, vehicle efficiency, etc.) can trigger the non-linear change needed
48 for a transformation to take place (Pelling et al. 2015). Exploring synergies between climate-change
49 adaptation, mitigation and other sustainability priorities (such as biodiversity and social equity, for
50 instance) (Beg 2002; Burch et al. 2014; Shaw et al. 2014) may help to yield these transformative
51 outcomes, though data regarding the specific nature of these synergies is still emerging.

52
53 Socio-technical transition theory, on the other hand, explores the ways in which technologies such as
54 low-carbon vehicles or regenerative buildings are bound up in a web of social practices, physical

1 infrastructure, market rules, regulations, norms and habits (see, for example, Loorbach et al. 2017).
2 Radical social and technical innovations can emerge that ultimately challenge destabilized or
3 increasingly ineffective and undesirable incumbents, but path dependencies often stymie these
4 transition processes, suggesting an important role for governance actors (Burch 2017; Frantzeskaki et
5 al. 2012; Holscher et al. 2019).

6
7 Socio-technical transitions theory, on the other hand, explores the ways in which technologies such as
8 low-carbon vehicles or regenerative buildings are bound up in a web of social practices, physical
9 infrastructure, market rules, regulations, norms and habits (see, for example, Loorbach et al. 2017).
10 Radical social and technical innovations can emerge that ultimately challenge destabilized or
11 increasingly ineffective and undesirable incumbents, but path dependencies often stymie these
12 transition processes, suggesting an important role for governance actors (Burch 2017; Frantzeskaki et
13 al. 2012; Holscher et al. 2019).

14
15 This also reveals the large-scale macro-economic, political and cultural trends (or contexts) that may
16 reinforce or call into question the usefulness of current systems of production and consumption. One
17 branch of this theory, transition management (Kern and Smith 2008; Loorbach 2010), explores ways of
18 guiding a socio-technical system from one path to another. In particular, it highlights interactions
19 between actors, technologies and institutions, and the complex governance mechanisms that facilitate
20 them (Smith et al. 2005). The challenge, in part, becomes linking radical short-term innovations with
21 longer-term visions of sustainability (Loorbach and Rotmans 2010) and creating opportunities for
22 collaborative course-correction in light of new information or unexpected outcomes (Burch 2017).

23 24 **17.2.5 Conclusions**

25 This section has surveyed several explanations for interventions that can give rise to transitions. The
26 review suggests that there are several differences between these various perspectives. Whether
27 individuals, organisations, markets or sociotechnical systems drive or undermine transitions is a key
28 distinction. These differences have implications for the evidence these claims draw on in support of
29 their arguments. For instance, some of the explanations tend to employ qualitative evidence to explain
30 changes in attitudes at the individual or community levels as paving the way for broader changes to
31 cultures and belief systems. Others assess how institutional arrangements can be reformed in order to
32 align climate with the sustainable development agenda to enable a transition.

33
34 While there are indeed significant differences between explanations, there are also important parallels.
35 Such parallels begin with a shared emphasis on synergies and trade-offs between climate and
36 sustainable development. Most explanations tend to underline the importance of synergies in aligning
37 the climate with broader sustainability agendas. Most importantly, many of the explanations are
38 complementary with the systems-level discussion in that they offer a broad framework, while economic,
39 psychological and governance theories offer more specific insights. Moving a transition forward will
40 often require drawing upon insights from multiple schools of thought. Though is unlikely that a one-
41 size-fits-all set of factors will drive a transition, there is a growing body of empirical evidence shedding
42 light on the factors that can strengthen synergies between climate and the broader sustainable
43 development agenda.

44 45 46 **17.3. Assessment of the results of studies where decarbonisation transitions 47 are framed within the context of sustainable development**

48 **17.3.1 Introduction**

49 This section assesses studies based on the links between sustainable development and climate change
50 mitigation in order to facilitate robust conclusions on synergies and trade-offs between different policy

1 objectives across methodologies, scenarios and sectors. Conclusions are drawn based on national and
2 sub-national, sectoral and cross-sectoral, short- and long-term transition studies presented in this and
3 other sections of the report as a basis for establishing an overall picture of how sustainable development
4 and climate change policies can be linked as a basis for accelerated transitions

5
6 This section focuses initially on issues related to short- and long-term transitions to meet climate change
7 and sustainable development goals in the context of the UNFCCC and the UN 2030 Agenda for
8 Sustainable Development. Global-modelling results and economy-wide studies are then assessed,
9 followed by a discussion of specific challenges in relation to renewable energy penetration and phasing
10 out fossil fuels, stranded assets and just transitions. Key synergies and trade-offs between meeting the
11 UN 2030 sustainable development goals (SDGs) and mitigation are then illustrated by means of cross-
12 sectoral examples. Finally, an overview of the assessment of SDG synergies and trade-offs based on all
13 sectoral chapters in this report for a range of key mitigation options is then presented.

14 15 **17.3.2 Short-term and long-term transitions**

16 It is increasingly being recognised that sustainable-development policy goals and meeting short- and
17 long-term climate policy goals are closely linked (IPCC 2018). It is also being realised that, under the
18 Paris Agreement, climate change policies should be integrated into sustainable development agendas,
19 while the UN 2030 Agenda as well includes SDG 13 on climate actions. In this way, both UN
20 agreements provide joint opportunities for systematic transitions in support of both climate change and
21 sustainable development. Achievement of the Paris Agreement's goals will require a rapid and deep
22 worldwide transition in all GHG emissions sectors, including land-use, energy, industry, buildings,
23 transport and cities, as well as in consumption and behaviour (United Nations Environment Programme
24 2019). Meeting the goals of such a transformation requires that the long-term targets and pathways to
25 fulfil the stabilization scenarios play an important role in guiding the direction and pathways of short-
26 term transitions. There is therefore a need for long- and short-term policies and investment decisions to
27 be closely coordinated.

28
29 In the context of the Paris Agreement, countries have submitted their initial plans for the
30 decarbonization of their economies to the UNFCCC in the form of their so-called national determined
31 contributions (NDCs). The ambitions of the NDCs are closely related to the ongoing UNFCCC
32 negotiations over the financial measures and forms of compensation. Although the Paris Agreement
33 emphasizes the links between climate policies and sustainable development, the UN's 2030 Agenda
34 and the SDGs are not very well represented at present in the NDCs, according to Fuso Nerini et al.
35 (2019). Very few of the NDCs include any reference to the SDGs, which Fuso Nerini et al. (2019)
36 highlight as a barrier to the successful implementation of the Paris Agreement, which induces them to
37 call for a more holistic policy approach. Campagnolo and Davide (2019) have assessed the impacts of
38 the submitted NDCs on poverty eradication and inequalities of income based on empirical research and
39 a global CGE model. One conclusion is that the NDCs of less developed countries would tend to reduce
40 poverty alleviation, but this can be offset if international financial support is provided for the mitigation
41 actions.

42
43 The alignment of climate-policy targets in the NDCs with sustainable development has been assessed
44 by means of integrated assessment models (IAMs), macroeconomic and sectoral modelling. Iyer et al.
45 (2018) based on IAM-based studies, the implications of framing NDCs being placed more narrowly on
46 mitigation targets rather than on a framing in which the impacts on sustainable development were
47 explicitly taken into consideration. It was thus concluded that some SDGs would be directly supported
48 as a side benefit of the climate policy targets included in the NDCs, while other SDGs needed a special
49 policy design going beyond narrow climate policy objectives. Iyer et al. (2018) also assessed the
50 regional distribution of efforts in terms of domestic mitigation costs and SDG impacts and concluded
51 that the geographical distribution of mitigation costs and SDG benefits were not similar, so a special
52 effort would be needed to match climate policies and policies to meet the SDGs. Accordingly, a national
53 decision-making perspective suggests that SDGs should be integrated into national climate policies.

1 The NDCs submitted to the Paris Agreement have demonstrated a lack of progress in meeting the long-
2 term temperature goals. In the context of the UN's 2030 Agenda, the UN Sustainable Development
3 Report 2019 (Sachs et al. 2019) also concluded that there is a particular lack of progress in achieving
4 SDG 13 (Climate action), SDG 14 (Life below water) and SDG 15 (Life on land). Given the close link
5 between the SDGs and climate-change policies, the current obstacles in meeting the former could also
6 be a barrier to realizing transitions to low-carbon societies. Conversely, opportunities to leverage the
7 SDGs could in many cases involve climate actions, since policies enabling climate adaptation and
8 mitigation could also support food and energy security and water conservation if they were well
9 designed (see the detailed discussion in the section on synergies and trade-offs between climate policies
10 and meeting the SDGs in section 17.3.3.7, Chapter 3 and IPCC 2018). These findings point to a specific
11 need to align economic and social development perspectives, climate change and natural systems. While
12 all countries share the totality of the SDGs, development priorities differ across countries and over time.
13 These priorities are strongly linked to local contexts and depend on which dimension of the
14 improvement in the well-being of people is considered to be the most urgent. Eradicating poverty and
15 reducing inequality are key development priorities for many low- and middle-income countries.
16 (Section 4.3.2.1 in Chapter 4).

17
18 A key barrier to the development of national plans and policies to meet the UN 2030 SDG goals is the
19 lack of finance. Sachs et al. (2019) conclude that meeting the SDGs to achieve social transformations
20 worldwide would require 2-3% of global GDP and that it would be a huge challenge to ensure that
21 finance is targeted to the world's poorest countries and people. The UN Secretary General has called
22 for the allocation of finance to meet the UN's 2030 Agenda with a strong emphasis on the private sector,
23 but to date no governance frameworks or associated financial modalities have been established in the
24 UN or the UNFCCC context for the formal alignment of sustainable development and transitions to
25 take place in accordance with the low global temperature-stabilization targets in the Paris Agreement.
26 Accelerating investments particularly in low-income countries will be required to meet both the Paris
27 goals and the SDGs (Section 15.6.7 in Chapter 15). The mismatch between capital and investment
28 needs, home bias considerations and differences in risk perceptions between rich and poor represent
29 major challenges for private finance. Green bond markets and markets for sustainable financial products
30 have increased significantly, and the landscape has continued to evolve since AR5 (Executive Summary
31 in Chapter 15). Special efforts and activities are particularly required for raising finance in developing
32 countries.

33
34 Based on the Paris Agreement, the UNFCCC has invited countries to communicate their mid-century
35 and long-term low greenhouse-gas emission-development strategies by 2020 (UNFCCC 2019).
36 National long-term low-emission development strategies and their global stocktake in the UNFCCC
37 context provide a platform for informing the long-term strategic thinking on transitions towards low-
38 carbon societies. One specific value of these plans is that they reflect how specific transition pathways,
39 policies and measures can work in different parts of the world in a very context-specific way, that is,
40 by taking context-specific issues and stakeholder perspectives into consideration. Many nations have
41 submitted national long-term strategies to the UNFCCC, including sustainable development
42 perspectives (See Section 4.2.4, 'Mid-century low-emission strategies at the national level' in Chapter
43 4 for a review of the plans and scientific assessments).

44 ***17.3.2.1 Model assessments on the sustainable development pathways for decarbonization***

45 This section assesses the model evaluations of the sustainable development pathways for
46 decarbonization, including the co-benefits and trade-offs involving explorations of alternative future
47 development pathways as a basis for clarifying societal objectives and understanding the restrictions.
48 Shifting development pathways to increased sustainability involves a number of complex issues, which
49 are difficult to integrate into models. For a more detailed discussion about this, see Section 4.4.1 in
50 Chapter 4 and the Cross-Chapter Box 5 in Chapter 4.

51
52
53 Development pathways that focus narrowly on climate mitigation or economic growth will not lead to
54 the SDGs and long-term climate-stabilization objectives being achieved. The best chances of doing this

1 lie in development pathways that can maximize the synergies between climate mitigation and
2 sustainable development more broadly (Section 1.3.2 in Chapter 1). Areas of focal modelling include
3 green investments, technological change, employment generation and the performance of policy
4 instruments, such as green taxes, subsidies, emission permits, investments and finance. Short- and long-
5 term macroeconomic models have been used to assess the impacts of such policy instruments. Jaumotte
6 et al. (2021) analyse the economic impacts on net zero emissions by 2050 with a focus on short-term
7 economic policies and the integration of climate policies such as CO₂ taxes with green reform policies.
8 This may imply the co-creation of benefits between climate policy objectives, and macroeconomic
9 policy goals such as employment creation.

10
11 There is an emerging modelling literature focusing on the synergies and trade-offs between low-carbon
12 development pathways and various aspects of sustainable development. The early literature, including
13 that on IAMs, and macroeconomic and sectoral models mainly focused on the co-benefits of mitigation
14 policies in terms of reduced air pollution, energy security and to some extent employment generation
15 security (IPCC 2014, 2018c; WGIII AR6 Chapter 6). Some models have been developed further with
16 assessments of a broader range of the joint benefits of mitigation, health, water, land-use and food
17 security (Clarke et al. 2014; IPCC 2014, 2018; Kolstad et al. 2014). According to WGIII AR6 Chapter
18 1, there is a need to incorporate issues and enablers further, including a wide range of non-climate risks,
19 varying forms of innovation, possibilities for behavioural and social change, feasible policies and equity
20 issues (Executive Summary in Chapter 1).

21
22 IAMs and macroeconomic models typically calculate mitigation costs based on the assumption that
23 markets internalise externalities like GHG emissions through carbon prices (Barker et al. 2016; IEA
24 2017, 2019). Yet, there are legitimate questions to be asked about whether carbon-pricing will be
25 efficient if markets are inefficient (World Bank 2019). However, market inefficiencies are difficult to
26 integrate into the models. How GHG emissions taxes would actually work is thus quite uncertain based
27 on the modelling studies (Barker et al. 2016; Fontana and Sawyer 2016; Meyer et al. 2018). Despite
28 these limitations, the use of GHG emission taxes as an effective instrument based on modelling results
29 in practice has implications for public policies and private-sector investments.

30
31 Despite the shortcomings of conventional economic thought and models, already pointed out, improved
32 models have demonstrated new perspectives on how mitigation costs can be assessed in macroeconomic
33 models. For instance, while a conventional perspective might suggest that climate-change mitigation
34 costs can limit investments in sustainability because they reduce the productivity of capital by
35 increasing energy prices and the products in which energies are embodied, another perspective is that
36 innovation can imply increases in efficiency and that the substitution of energy, material and labour can
37 lead to the accumulation of capital and productivity gains. This appears to occur with innovations in
38 end-use energy applications generating emissions reductions and delivering on other sustainable
39 development benefits (Wilson et al. 2019). Similarly, IAM models have been applied to model the
40 potential for low energy demand scenarios associated with demand-side innovations in the service
41 sector. Grubler et al. (2018) have developed a climate-friendly, low-energy demand (LED) scenario
42 which assumes information technology innovations such as the internet of things (IoT) and induced
43 social changes such as the sharing economy. Nonetheless there are still very important limits on the
44 degree to which highly aggregated IAM models and macroeconomic models can integrate ethics, equity
45 and several other key policy-relevant aspects of sustainable development (Easterlin et al. 2010; Koch
46 2020). A key limitation in this context is that, while all countries share the totality of the SDGs,
47 development priorities differ across countries and over time. Moreover, these priorities are strongly
48 linked to local contexts, and this can only be reflected directly in national models (Section 4.3.2 in
49 Chapter 4).

50
51 An example of a project that assesses the economy-wide impacts of linking sustainable development
52 with deep decarbonization is the deep decarbonization project or DDPP (Bataille et al. 2016), which is
53 undertaking a comparative assessment of studies of sixteen countries representing more than 74% of
54 global energy-related emissions for the pathway to two-degree stabilization scenarios. The DDDP's
55 methodology is to combine scenario analysis in different national contexts using macroeconomic

1 models and sectoral models and to facilitate a consistent cross-country analysis using a set of common
2 assumptions.

3
4 The key conclusions of the DDPP team on the economy-wide impacts are that country studies like
5 South Africa's demonstrate that it is possible to improve income distribution, alleviate poverty and
6 reduce unemployment while simultaneously transitioning to a low-carbon economy (Altieri et al. 2016).
7 The DDPP in Japan explores whether energy security can be enhanced through increases in renewable
8 energy (Oshiro et al. 2016). The reduction of uncontrolled fossil-fuel emissions has significant public-
9 health benefits according to the Chinese and Indian DDPPs, as fossil-fuel combustion is the major
10 source of air pollution.

11
12 For example, in the Chinese DDDP, deep decarbonization scenarios have resulted in reductions of 42–
13 79% in primary air pollutants (e.g., SO₂, NO_x, particulate matter (PM_{2.5}), volatile organic compounds
14 (VOCs), and NH₃), thus meeting air-quality standards in major cities. The deep decarbonization
15 scenarios include the large and fast energy-efficient improvements required to improve energy access
16 and affordability. The DDPP studies are thus an example of an approach in which national deep-
17 carbonization scenarios are linked to the development goals of income generation, energy access and
18 affordability, employment, health and environmental policy.

19
20 Sustainable development scenarios have also been developed by the Low-Carbon Society's (LCS)
21 assessments (Kainuma et al. 2012), in which multiple sustainable development and climate change
22 mitigation goals were assessed jointly. The scenario analysis was conducted for Asian countries such
23 as South Korea, Japan, India, China and Nepal with a soft linked IAM using economy-wide and sectoral
24 models and linked to very active stakeholder engagement in order to reflect national policy perspectives
25 and priorities. Some of the models are economy-wide global IAMs, while others are national partial
26 equilibrium models.

27
28 The LCS scenarios also include a specific attempt to include ongoing dialogues with policy-makers and
29 stakeholders in order to reflect governance and enabling factors and to enable the modelling processes
30 to reflect political realism as far as possible. Diverse stakeholders who acted as validators of the
31 scientific process were included, stakeholder preferences were revealed, and recipients and users of the
32 LCS outputs were included in ongoing dialogues on outputs and in interpreting the results. The aim of
33 the stakeholder interactions was thus to fill the gap between typical laboratory-style integrated
34 modelling assessments and down-scaled but unaligned practical assessments performed at
35 disaggregated geographical and sector-specific scales.

36
37 Energy scenarios for sustainable development were included in The World Energy Outlook of the IEA
38 (IEA 2019, 2020) in terms of a Sustainable Development Scenario (SDS), which assessed not only SDG
39 13 (climate change) but also SDG 7 (energy access) and SDG 3.9 (air pollution). This scenario takes as
40 its starting point the policy goal of meeting these SDGs and then assesses the costs of meeting an
41 emissions reduction target of 70% of CO₂ from the energy system by 2030. The scenario concludes that
42 retrofitting coal-fired power plants with pollution controls is the cheapest option for dealing with local
43 pollution in the short term, but that this is not consistent with meeting the long-term emissions goals of
44 the Paris Agreement. The SDS scenario combines the goal of reducing the amount of CO₂ in the energy
45 system by 70%, with large decreases in energy-related emissions of NO_x, SO₂ and PM_{2.5}, leading to a
46 fall of 40–60% by 2030, and to 2.5 million fewer premature deaths from air pollution in 2030 than in
47 the Stated Policies Scenario (STEPS), which represent a continuation of current trends in the energy
48 system (IEA 2020).

49
50 The costs of energy-system transitions have been assessed by several energy-system studies. The
51 economic costs of meeting the different goals depend on the stringency of the mitigation target, as well
52 as economic (fuel prices etc.) and technological developments (technology availability, capital costs
53 etc.). In addition, changes in infrastructure and behavioural patterns and lifestyles matter. Model-based
54 assessments vary, depending on these assumptions and differences in modelling approaches (Krey et
55 al. 2019; Section 6.7.7 in Chapter 6). Country characteristics determine the social, economic and

1 technical priorities for low-emission pathways. Domestic policy circumstances impact on pathways and
2 costs, e.g. when affordability and energy-security concerns are emphasized (Oshiro et al. 2016).

3
4 Mitigation policies can have important distributive effects between and within countries, and may affect
5 impact on the poorest through their effects on energy and food prices (Section 3.6.4 in Chapter 3;
6 Hasegawa et al. 2018; Fujimori et al. 2019), while higher levels of warming are projected to generate
7 higher inequality between countries as well as within them (Chapter 16). Mitigation thus can reduce
8 economic inequalities and poverty by avoiding such impacts (Section 3.6.4 in Chapter 3).

9
10 Improved air quality and the associated health effects are the co-benefit category dominating model-
11 based assessments of co-benefits, but a few studies have also covered other aspects, such as the health
12 effects of dietary change and biodiversity impacts (Section 3.6.3 in Chapter 3 and Section 17.3 of this
13 chapter). Mitigation has implications for global economic inequalities through different channels and
14 can compound or lessen inequalities, avoid impacts and create co-benefits that reduce inequalities
15 (Section 3.6.4 in Chapter 3). There are, however, several challenges involved in balancing the dilemmas
16 associated with meeting the SDGs, such as, for example, energy access, equity and sustainability. Fossil
17 fuel-dependent developing countries cannot transit to low-carbon economics without considering the
18 wider impacts on development by doing so (Section 3.7.3 in Chapter 3).

19
20 Climate change has negative impacts on agricultural productivity in general, including unequal
21 geographical distribution (Chapter 3). On top of that, there is also a risk that climate-change mitigation
22 aimed at achieving stringent climate goals could negatively affect food access and food security
23 (Akimoto et al. 2012; Fujimori et al. 2019; Hasegawa et al. 2018). If not managed properly, the risk of
24 hunger due to climate policies such as large-scale bioenergy production increases remarkably if the 2
25 °C and 1.5 °C targets are implemented (Section 3.7.1 in Chapter 3). Taking the highest median values
26 from different IAMs for given classes of scenarios, up to 14.9 GtCO₂ yr⁻¹ carbon dioxide removal (CDR)
27 from BECCS is required in 2100, and 2.4 GtCO₂ yr⁻¹ for afforestation. Across the different scenarios,
28 median changes in global forest area throughout the 21st century reach the required 7.2 Mkm² increases
29 between 2010 and 2100, and agricultural land used for second-generation bioenergy crop production
30 may require up to 6.6 Mkm² in 2100, increasing the competition for land and potentially affecting
31 sustainable development (AR6 scenarios database).

32
33 Reducing climate change can reduce the share of the global population exposed to increased stress from
34 reductions in water resources (Arnell and Lloyd-Hughes 2014) and therefore to water scarcity as defined
35 by a cumulative abstraction-to-demand ratio (Hanasaki et al. 2013). Byers et al. (2018), show that 8–
36 14% of the population will be exposed to severe reductions in water supply if average temperatures
37 increase between 1.5 and 2.0 °C (also see Section 3.7.2 in Chapter 3). Hayashi et al. (2018) assess the
38 water availability for different emission pathways, including the 2°C and 1.5°C targets, in light of the
39 various factors governing availability. There are very different impacts among nations. In Afghanistan,
40 Pakistan and South Africa, water stress is estimated to increase by 2050 mainly due to increases in
41 irrigation water associated with the rising demand for food, and climate change will already increase
42 water stress within the next decades. Other factors, such as changes in the demand for municipal water,
43 water for electricity generation, other industrial water and water for livestock due to climate change
44 mitigation, are of limited importance.

45
46 Vandyck et al. (2018) estimate that the 2°C pathway would reduce air pollution and avoid 0.7–1.5
47 million premature deaths in 2050 compared to current levels. It is generally agreed that in both
48 developed and developing countries there are additional benefits of climate change mitigation in terms
49 of improved air quality (Section 3.7.4 in Chapter 3). Markandya et al. (2018) assessed the health co-
50 benefits of air pollution reductions and the mitigation costs of the Paris Agreement using global
51 scenarios for up to 2050. They concluded that the health co-benefits substantially outweighed the policy
52 costs of achieving the NDC targets and either 2°C or 1.5°C stabilization. The ratio of health co-benefits
53 to the mitigation costs ranged from 1.4 to 2.45, depending on the scenario. The extra effort of trying to
54 pursue the 1.5°C target instead of the 2°C target would generate a substantial net benefit in some areas.

1 In India, the co-health benefits were valued at USD3.28–8.4 trillion and those in China at USD0.27–
2 2.31 trillion. Gi et al. (2019) also show that developing countries such as India have a huge potential to
3 produce co-benefits. In addition, this implies that while the cost advantages of simultaneously achieving
4 reductions of CO₂ emissions and of PM_{2.5} are clear, the advantages for integrated measures could be
5 limited, as the costs greatly depend on the CO₂ emissions reduction target.
6

7 Grubler et al. (2018) models a pathway leading to global temperature change of less than 1.5°C without
8 CCS, taking end-use changes into account, including innovations in information technologies and
9 changes to consumer behaviour apart from passive consumption. The pathway estimates global final-
10 energy demand of 245 EJ/yr in 2050, which is much lower than in existing studies (also see Section
11 5.3.3 in Chapter 5). It also shows the possibilities of creating synergies between multiple SDGs,
12 including hunger, health, energy access and land-use. Integrated technological and social innovations
13 will increase the opportunity to achieve sustainable development. Millward-Hopkins et al. (2020)
14 estimates global final energy at 149 EJ/yr in 2050 as required to provide decent material living
15 standards, which is much lower than the 1.5 °C scenario ranges (330–480 EJ/yr in 2050) of IAMs (IPCC
16 2018) and the 390 EJ/yr in the IEA SDS (IEA 2019), and also lower than Grubler et al. (2018). The
17 conclusion is that, although providing material living standards does not guarantee that every person
18 will live a good life, there are large potentials in achieving low energy demand with sustainable
19 development.
20

21 An overview of the co-benefits and trade-offs of several SDGs based on modelling results is provided
22 in Figure 3.39 (Section 3.7 in Chapter 3). Selected mitigation co-benefits and trade-offs are provided in
23 relation to meeting the 1.5 degree temperature goal based on a subset of models and scenarios, despite
24 many IAMs so far not having comprehensive coverage of the sustainable development goals (Rao et al.
25 2017; van Soest et al. 2019). There are several co-benefits of mitigation policies, including increased
26 forest cover (SDG 15) and reduced mortality from ambient PM_{2.5} pollution (SDG 3) compared to
27 reference scenarios. However, mitigation policies can also cause higher food prices and thus increase
28 the share of the global population at risk from hunger (SDG 2), while also relying on solid fuels (SDGs
29 7 & 3) as side effects. It is then concluded in Section 3.7 of Chapter 3, that these trade-offs can be
30 balanced through targeted support measures and/or additional SD policies (Bertram et al. 2018;
31 Cameron et al. 2016; Fujimori et al. 2019).
32

33 The World in 2050 Initiative (TWI) includes a comprehensive assessment of technologies, economies
34 and societies embodied in the SDGs (IIASA 2018). The assessment addresses social dynamics,
35 governance and sustainable development pathways within the areas of human capacity and
36 demography, consumption and production, decarbonization and energy, food, the biosphere and water,
37 smart cities and digitalization. The report concludes that the 17 SDGs are integrated and complementary
38 and need to be addressed in unison. Studies using global IAMs that were presented in the GEO6 report
39 (United Nations Environment Programme 2019, Chapter 22) concluded that transitions to low-carbon
40 pathways will require a broad portfolio of measures, including a mixture of technological
41 improvements, lifestyle changes and localized solutions. The many different challenges require
42 dedicated measures to improve access to, for example, food, water and energy, while at the same time
43 reducing the pressure on environmental resources and ecosystems. A key contribution may be a
44 redistribution of access to resources, where both physical access and affordability play a role. The IAMs
45 cover large countries and regions, and localized solutions are not properly addressed in the modelling
46 results. This implies that, for example, trade-offs between energy access and affordability are not fully
47 represented in aggregate modelling results.
48

49 There are also several country-level studies for deep emissions reductions (see Chapter 4 for an
50 overview of the results). The studies find significant impacts of mitigation policies at the sectoral level,
51 reflecting the fact that the sectoral scope does not allow for as much flexibility in mitigation measures
52 despite macroeconomic impacts being assessed to be small (Executive Summary in Chapter 4).
53 Another key lesson is that the detailed design of mitigation policies is critical for the distributional
54 impacts (Executive Summary in Chapter 4). The potential mitigation measures, the potential economic

1 growth, the political priorities and so forth are different among nations, and there may be several
2 emissions reduction transition pathways to long-term goals among nations (Figure 4.2 in Chapter 4).

3 4 **17.3.2.2 Renewable energy penetration and fossil-fuel phase-out**

5 As pointed out in Chapter 6, the achievement of long-term temperature goals in line with the Paris
6 Agreement requires the rapid penetration of renewable energy and a timely phasing out of fossil fuels,
7 especially coal, from the global energy system. Limiting warming to 1.5°C with no or limited overshoot
8 means that global CO₂ emissions must reach “net zero” in 2050/2060 (IPCC 2018). Net zero emissions
9 imply that fossil fuel use is minimised and replaced by renewables and other low-carbon primary forms
10 of energy, or that the residual emissions from fossil fuels are offset by carbon dioxide removal. The
11 1.5°C scenario requires a 2-3% annual improvement rate in carbon intensities till 2050. The historical
12 record only shows a slight improvement in the carbon intensity rate of global energy supplies, far from
13 what is required to limit likely global warming to 2°C, or limit warming to 1.5°C with no or limited
14 overshoot.

15
16 The role of coal in the global energy system is changing fast. Given the global temperature goals of the
17 Paris Agreement, the global coal sector needs a transition to near zero by 2050 – earlier in some regions
18 (Bauer et al. 2018; IEA 2017; IPCC 2018). Other global trends, including air quality, water shortages,
19 the improved cost efficiencies of renewables, the technical availability of energy storage and the
20 economic rebalancing of emerging countries, are also driving global coal consumption to a plateau
21 followed by a reverse (Sator 2018; Spencer et al. 2018). The world should be prepared for a managed
22 transition away from coal and should identify appropriate transition options for the future of coal, which
23 can include both the penetration of renewable energy and improvements in energy efficiency (Shah et
24 al. 2015).

25
26 Phasing out fossil fuels from energy systems is technically possible and is estimated to be relatively
27 low in cost (Chapter 6). The cost of low-carbon alternatives, including onshore and offshore wind, solar
28 PV and electric vehicles, has been reduced substantially in recent years and has become competitive
29 with fossil fuels (Shen et al. 2020). However, studies show that replacing fossil fuels with renewables
30 can have major synergies and trade-offs with a broader agenda of sustainable development (Swain and
31 Karimu 2020), including land use and food security (McCullum et al. 2018), decent jobs and economic
32 growth (Swain and Karimu 2020). Clarke et al. (2014:Table 6.7) provides detailed mapping of the
33 sectoral co-benefits and adverse side-impacts of and links to transformation pathways. In Section
34 17.3.3.7 in this chapter, this is supplemented with a mapping of the synergies and trade-offs between
35 the deployment of renewable energy and the SDGs.

36
37 The general conclusion is that the potential co-benefits of renewable energy end-use measures outweigh
38 the adverse impacts in most sectors and in relation to the SDGs, though this is not the case for the
39 AFOLU (Agriculture, Forestry and Other Land Uses) sectors. Some locally negative economic impacts
40 can result in increased energy costs and competition over land areas and water resources. Some sectors
41 may also experience increasing unemployment as a consequence of the transition process. Although the
42 deployment of renewable energy will generate a new industry and associated jobs and benefits in some
43 areas and economies, these impacts will often not directly replace or offset activities in areas that have
44 been heavily dependent on the fossil-fuel industry.

45
46 The transition to low emission pathways will require policy efforts that also address the emissions that
47 are locked into existing infrastructure like power plants, factories, cargo ships and other infrastructure
48 already in use: for example, today coal-fired power plants account for 30% of all energy-related
49 emissions (IEA 2019). Over the past twenty years, Asia has accounted for 90% of all coal-fired capacity
50 built worldwide, and these plants have potentially long operational lifetimes ahead of them. In
51 developing economies in Asia, existing coal-fired plants are just twelve years old on average. There are
52 three options for bringing down emissions from the existing stock of plants: to retrofit them with carbon
53 capture, utilisation and storage (CCUS) or biomass co-firing equipment; to repurpose them to focus on
54 providing system adequacy and flexibility while reducing operations; and to retire them early. In the

1 IEA Sustainable Development Scenario, most of the 2080 GW of existing coal-fired capacity would be
2 affected by one of these three options.

3
4 Even though the transition away from fossil fuels is desirable and technically feasible, it is still largely
5 constrained by existing fossil fuel-based infrastructure and stranded investments. The “committed”
6 emissions from existing fossil-fuel infrastructure may consume all the remaining carbon budget in the
7 1.5°C scenario, or two thirds of the carbon budget in the 2°C scenario (Tong et al. 2019). Kefford et al.
8 (2018) assess the early retirement of fossil-fuel power plants in the US, EU, China and India based on
9 the IEA 2°C scenario and conclude that a massive early retirement of coal-fired power plants is needed,
10 and that two to three standard 500 MW generators will need to come offline every week for fifteen
11 years. This high rate is the result of a very large deployment of coal-fired power plants from 2004 to
12 2012. The early phasing out of this infrastructure will result in a significant share of stranded assets
13 (Ansari and Holz 2020) with an impact on workers, local communities, companies and governments
14 (van der Ploeg and Rezaei 2020). The challenge is thus to manage a transition which delivers the rapid
15 phasing out of existing fossil fuel-based infrastructure while also developing a new energy system based
16 on low-carbon alternatives within a very short window of opportunity.

17
18 Chapter 6 similarly concludes that the transition towards a high penetration of renewable systems faces
19 various challenges in the technical, environmental and socio-economic fields. The integration of
20 renewables into the grid requires not only sufficient flexibility in power grids and intensive coordination
21 with other sources of generation, but also a fundamental change in long-term planning and grid
22 operation (see Chapter 6 for more details on these issues).

23 Examples from various countries show that, compared with top-down decision-making, bottom-up
24 policy-making involving local stakeholders could enable regions to benefit and reduce their resistance
25 to transitions. Kainuma et al. (2012) conclude that social dialogue is a critical condition for engaging
26 local workers and communities in managing the transitions with the necessary support from transition
27 assistance. They also point out that macro-level policies, training programmes, participatory processes
28 and specific programmes to support employment creation for workers in fossil fuel-dependent industries
29 are needed.

30
31 Examples of challenges in transitions away from using coal are given in Box 17.1.

32 33 **START BOX 17.1 HERE**

34 **Box 17.1 Case study: coal transitions**

35
36 The coal transition will pose challenges not only to the power sector, but even more importantly to coal-
37 mining. A less diversified local economy, low labour mobility and heavy dependence on coal revenues
38 will make closing down coal production particularly challenging from a political economy perspective.
39 Policy is needed to support and invest in impacted areas to smooth the transition, absorb the impact and
40 incentivize new opportunities. A supportive policy for the transition could include both short-term
41 support and long-term investment. Short-term compensation could be helpful for local workers,
42 communities, companies and governments to manage the consequences of coal closures. Earlier
43 involvement with local stakeholders using a structured approach is crucial and will make the transition
44 policy more targeted and better administered. The long-term policy should target support to the local
45 economy and workers to move beyond coal, including a strategic plan to transform the impacted area,
46 investment in local infrastructure and education, and preference policies to incentivize emerging
47 businesses. Most importantly, ex-ante policy implementation is far better than ex-post compensation.
48 Even without the climate imperative, historical evidence shows that coal closures can happen
49 surprisingly fast.

50
51 Coal has hitherto been the dominant energy source in China and has accounted for more than 70% of
52 its total energy consumption for the past twenty years, falling to 64% in 2015 (The National BIM Report
53 2018). In the 13th Five Year Plan (2016-2020), for the first time China included the target of a national
54 coal consumption cap of 4.1 billion tons for 2020, as well as a goal of reducing the primary energy

1 share of coal to 58% by 2020 from the level of 64% in 2015 (The National People’s Congress of the
2 People’s Republic of China 2016). The main driving forces of the coal transition in China are increasing
3 domestic environmental concerns and the pressure to reduce greenhouse gas emissions. Coal
4 combustion contributes about 90% of total SO₂ emissions, 70% of NO_x emissions and 54% of primary
5 PM_{2.5} emissions in China (Yang and Teng 2018). The early phasing out of coal also delivers a co-
6 benefit in terms of reductions of air pollutants that are consistent with China’s goal to improve air
7 quality (Zhang et al. 2019), as well as the reduction of methane (Teng et al. 2019) and black carbon
8 (Zhang et al. 2019). The coal transition in China will change the future value of coal-related assets, and
9 both coal power generators in China and coal producers outside China need to identify appropriate
10 responses to avoid and manage the potentially substantial stranding of fossil-fuel assets. A rapid
11 transition away from coal is critical for China to reach the peak in its emissions (Cui et al. 2019). Despite
12 the deployment of CCS and extending the use of coal, retrofitting CCS plant may be more expensive
13 than deploying renewables (IEA 2019).

14
15 Presently, coal-fired power plants play a key role in the German energy system, providing almost 46%
16 of the electricity consumed in Germany. These coal power plants play a crucial role in balancing
17 fluctuations in producing electricity from renewables (Parra et al. 2019). Political and economic
18 considerations, at least regionally, are also of great importance in the coal sector due to the
19 approximately 35,000 people employed within it (including coal-mining and the power stations
20 themselves). For a long time, coal-fired power plants were able to protect their position in Germany,
21 but against the background of decreasing public acceptance, economic problems resulting from the
22 growing use of renewables and ambitious GHG reduction targets, the sector cannot resist the political
23 pressures against them any longer. The governing parties have agreed to establish a commission called
24 “Growth, structural change and employment” to develop a strategy for phasing out coal-fired power
25 plants (E3G Annual Review 2018). This Commission consists of experts and stakeholders from
26 industry, associations, unions, the scientific community, pressure groups and politicians. Its
27 establishment shows that the phasing-out process deserves close attention and that management policies
28 must be implemented to ensure a soft landing for the electricity sector.

29 **END BOX 17.1 HERE**

30
31 The transition towards a high-penetration renewable system also raises concerns over the availability
32 of rare metals for batteries like lithium and cobalt. While metal reserves are unlikely to limit the growth
33 rate or total amount of solar and wind energy, used battery technologies and the known reserves
34 currently being exploited are not compatible with the transition scenario due to insufficient cobalt and
35 lithium reserves (Månberger and Stenqvist 2018). Global lithium production rose by roughly 13 percent
36 from 2016 to 2017 to 43,000 MT in 2018 (Golberg 2021). Africa has rich reserves of lithium and is
37 expected to produce 15% of the world’s supply soon (Rosenberg et al. 2019). Such reserves are found
38 in Zimbabwe, Botswana, Mozambique, Namibia, South Africa (Steenkamp 2017) and the Democratic
39 Republic of Congo (Roker 2018).

40
41 The demand for these resources as ingredients in rechargeable batteries is growing rapidly, with global
42 demand for cobalt set to quadruple to over 190,000tn by 2026. The DRC is a mineral-rich country
43 (Smith et al. 2019a) with rich reserves of fossil fuels (coal and oil) (Buzananakova 2015). The extraction
44 of lithium and cobalt can be environmentally and socially damaging, though its use as a principal
45 component in most rechargeable batteries for electric vehicles and electronic smart grids affords it high
46 sustainability value. Chapter 10 includes a more detailed assessment of the issues with mining these
47 rare metals, as well as the associated social problems, including exploitative working conditions and
48 child labour, the latter a major issue that needs to be taken into consideration in transitions. Recycling
49 batteries is also highlighted as a major supplementary policy if negative environmental side impacts are
50 to be avoided (Rosendahl and Rubiano 2019). In the future, more attention should be paid to reducing
51 vulnerability through subsidizing R&D in rare metals recycling, establishing systems to incentivize the
52 collection of rare-metal waste and promoting technological progress using abundant metals as a
53 replacement for rare metals (Rosendahl and Rubiano 2019).

1 Chapter 10 also provides a more detailed assessment of the issues involved in mining these rare metals,
2 as well as the associated social problems, including exploitative working conditions and child labour,
3 the latter a major issue that needs to be taken into consideration in transitions. Recycling batteries is
4 also highlighted as a major supplementary policy if negative environmental side impacts are to be
5 avoided (Rosendahl and Rubiano 2019).

6 7 *17.3.2.3 Stranded assets, inequality and just transitions*

8 As the momentum towards achieving carbon neutrality grows, the risk of certain assets becoming
9 stranded is on the increase. International policies and the push for low-carbon technologies in the
10 context of climate change are reducing the demand for and value of fossil-fuel products. Stranded assets
11 become devalued before the end of their economic life or can no longer be monetised due to changes in
12 policies and regulatory frameworks, technological change, security, or environmental disruption. In
13 short, stranded assets are “assets that have suffered from unanticipated or premature write-down,
14 devaluations or conversions to liabilities” (Caldecott et al. 2013).

15
16 Stranded assets are likely to “lose economic value ahead of their anticipated useful life” (Bos and Gupta
17 2019). They are often described as creative when they become stranded because of innovation,
18 competition or economic growth (Gupta et al. 2020). Divestment refers to “the action or process of
19 selling off subsidiary business interests or investments.” This often occurs due to changing social norms
20 and perceptions of climate change.

21
22 Indeed, pressure is mounting on fossil-fuel industries to remove their capital from heavy carbon
23 industries. As the former Governor of the Bank of England, Mark Carney, remarked, a wholesale
24 reassessment of prospects, especially if it were to occur suddenly, could potentially destabilise markets,
25 sparking a pro-cyclical crystallisation of losses and a persistent tightening of financial conditions. In
26 other words, an abrupt resolution to the tragedy of horizons itself poses a risk to financial stability
27 (OECD 2015). The divestment narrative is also based on the view that a shift away from intensive
28 carbon resources will be significant, as the “less value will be destroyed, [...] the more can be re-
29 invested in low carbon infrastructure” (OECD 2015). Social movements are critical to triggering rapid
30 transformational change and moving away from dangerous levels of climate change (Mckibben 2012).
31 Although divestment is hailed as a necessary action to decouple fossil fuel from growth and force
32 carbon-intensive industries to go out of business, there is the sense that there is no shortage of investors
33 who are willing to buy shares, so that such resources are not stranded, but simply relocated. Criticism
34 has been levelled at the divestment movement for not having a significant impact on funding fossil fuels
35 and not being sufficiently in tune with other wide-ranging complexities that go beyond the moral
36 dimensions (Bergman 2018). Despite being labelled a ‘moral entrepreneur’, the divestment movement
37 has the potential to disrupt current practices in the fossil-fuel industry, shape a ‘disruptive innovation’
38 and contribute to a strategy for decarbonising economies globally (Bergman 2018). Divestment is
39 contributing to the political situation that is ‘weakening the political and economic stronghold of the
40 fossil fuel industry’ (Grady-Benson and Sarathy 2016).

41
42 The risks attached to the stranding of fossil-fuel assets have increased with the recent and sustained
43 plunge in oil prices because of the global health pandemic (COVID-19) and the concomitant economic
44 downturn, forcing demand to plummet to unprecedentedly low levels. (Oil prices have recently
45 increased). Many economies in transition and countries dependent on fossil fuels are going through
46 turbulent times where asset and transition management will be critical (UNEP/SEI 2020). However,
47 COVID-19 provides a foretaste of what a low-carbon transition could look like, especially if assets
48 become stranded in an effort to respond to the call for action in ‘building back better’ and putting clean
49 energy jobs and the just transition at the heart of the post-COVID-19 recovery (IEA 2020; United
50 Nations General Assembly 2021). COVID-19 provides a useful proxy for issuing two alerts. First, it is
51 a reminder of the urgency of addressing climate change, given that delaying the move away from
52 stranded assets will further worsen climate change. Second, failure to recognize the threat from stranded
53 assets will result in new assets becoming stranded (Rempel and Gupta 2021). Hence, the momentum
54 towards a transformational push is resting on a new opportunity ushered in by COVID-19 to emphasize
55 the urgency for a new departure towards rapid emissions reductions (Cronin et al. 2021).

1
2 The stranded assets narrative has focused overwhelmingly on consumption by companies: not much
3 emphasis has been placed on the commercialisation- and investment-related aspects. In addition, other
4 carbon-intensive activities can also run the risk of being stranded, such as cement, petrochemicals, steel
5 and aviation (Baron and David 2015). This is why stranded assets are often referred to as having a
6 cascading impact on several other sectors.

7
8 Transitions are broad-based and complex, involving governance structures, institutions and climate
9 vulnerabilities, and there is need to include historical responsibility, resource intensity and capacity
10 differentials, thus relegating the debate across simplistic binary lines of developed versus developing
11 countries (Carney 2016). Hence, transition processes will have to respond to several preconditions and
12 structural inequalities related to climate finance, energy poverty, vulnerabilities and the broader macro-
13 economic implications associated with managing the debt burden, fiscal deficits and uneven terms of
14 development in developing countries. In addition to structural inequalities, the COVID-19 pandemic
15 has severely disrupted energy and food systems to and reduced the speed at which developing countries
16 can procure new low-carbon technologies and decouple economic growth from fossil fuels (Winkler
17 2020). For instance, global supply-chain transition costs might be lower when compared to in-country
18 supply chains, as became evident when COVID-19 created further disruption to renewable energy
19 projects (Cronin et al. 2021). Moreover, developing countries can experience difficulties in phasing out
20 old technologies, especially if the latter has a cost disadvantage, has not benefitted from an established
21 track record and its performance is uncertain (Bos and Gupta 2019). There is the risk of lock-in effects
22 related to grandfathering when emitters comply with less stringent standards.

23 Despite their efforts in deploying renewable energies, many developing countries are still contending
24 with problems related to the immaturity of the current technologies and the challenges of battery
25 storage. In short, the transition to a low carbon development must consider the challenges of renewable
26 energy penetration and existing energy-related vulnerabilities and inequalities. There are power
27 asymmetries between first-comers and latecomers, especially in cases where mature technologies can
28 be located in countries with less stringent laws and standards. Carbon leakage has implications for just
29 transitions, as carbon-intensive industries can move their dirty industries to developing countries as a
30 way of outsourcing the production of carbon (Bos and Gupta 2019; UNU-INRA 2020, Denton et al,
31 2021). When the challenge of climate mitigation is transferred to developing countries in the form of
32 carbon leakage, the risks of carbon lock-in for developing countries are heightened (Bos and Gupta
33 2019).

34 Overcoming the carbon lock-in is not simply a matter of the right policies or switching to low-carbon
35 technologies. Indeed, it would mean a radical change in the existing power relations between fossil-fuel
36 industries and their governments and social structural behaviour (Seto et al. 2016). Some actions to fix
37 the climate change problem can themselves create injustices, thereby challenging sustainable
38 development (Cronin et al. 2021). Not paying sufficient attention to perceptions of injustice related to
39 the rights to development, energy and resource sovereignty can further create resistance to climate
40 action (Cronin et al. 2021).

41 The shrinking carbon budget has raised questions over whether to meet our commitment to 2 degrees
42 Celsius if fossil-fuel resources were to be mined or left stranded, as McGlade and Ekins argue: '... [a]
43 large portion of the reserve base and an even more significant proportion of the resource base should
44 not be produced if the temperature rise is to remain below 2 degrees C' (McGlade and Ekins 2015).
45 This logic means that developing countries that rely on fossil-fuel extraction will need to replace their
46 hydrocarbon revenues with other income-generating activities. Stranded assets remind most oil-
47 producing governments that fossil-fuel assets do not have a durable value and are vulnerable to politico-
48 economic forces and fluctuations. The goal of staying within the 1.5°C temperature goal, in line with
49 the Paris Agreement, is already part of the policy vision and planning of large fossil fuel-consuming
50 economies. For early fossil-fuel producers, however, the reality that their resources may not yield the

1 desired returns is often perceived as bad news, particularly in the context of the increasing depreciation
2 of fossil-fuel products.

3
4 Stranded assets raise fundamental questions related to issues of equity and just transitions:

- 5
- 6 • Who decides which resources should be stranded?
- 7 • Who shoulders the burden of the transition and losses incurred from moving away from heavy
- 8 industries with associated compensation?
- 9 • How should the advantages of short-term fossil-fuel exploitation be shared based on the
- 10 principle of distributive justice?
- 11

12 The transition to a low-carbon development is wired in issues of justice and equity: how do you align
13 carbon reductions to meet the needs of humanity? Distributive justice calls for a fairer sharing of the
14 benefits and burdens of the transition process, while procedural justice is essentially about ensuring that
15 the demands of vulnerable groups are not ignored in the pull to the transition. The impacts of climate
16 change and the mitigation burdens are experienced differently by different social actors, with
17 indigenous communities facing multiple threats and being subjected to unequal power dynamics
18 (Sovacool 2021).

19
20 Nonetheless, the production of fossil fuels is central to many economies with numerous development
21 implications related to rents associated with export revenues, energy security and poverty alleviation
22 (Lazarus and van Asselt 2018). The central question is who decides which types of carbon should be
23 burnable or non-burnable. Hence, social equality is at the heart of the transition process, but it falls short
24 of a response on how to chart a new road map towards carbon neutrality, especially given that fossil-
25 fuel producers and investors tend to belong to large, powerful companies and wield a great deal of
26 influence and power, especially when their entrenched interests are at stake (Lazarus and van Asselt
27 2018). The question of whether developing countries should be compensated for foregoing their
28 resources in light of their current development needs has not yielded many results and had only limited
29 success in mobilising international finance, as demonstrated by the case of Yasuni-ITT in Ecuador
30 (Sovacool and Scarpaci 2016). According to Sovacool et al. (2021), affected communities and their
31 views may be discounted and excluded from planning, which can neglect important matters such as
32 rights, recognition and representation (Sovacool 2021).

33
34 Fossil fuel-dependent countries are doubly exposed to the vulnerability related to climate-change
35 impacts and are being targeted in the global effort to address the problem (Peszko et al. 2020). Countries
36 that are heavily reliant on oil, coal and gas are also those most at risk from a low-carbon transition that
37 may curtail the activities of their fossil-fuel industries and render the value chains and economies
38 associated with the exploitation of fossil fuels unviable (Peszko et al. 2020).

39
40 Developing countries in Latin America and Africa that are reliant on revenue streams from fossil fuels
41 may not see these returns converted into much needed infrastructure and other social and economic
42 amenities that can reduce poverty. However, given the falling prices of renewables, developing
43 countries do not have to face the burden of retrofitting their infrastructure to align with new low-carbon
44 industries, since they can leapfrog technologies and shape a sustainable trajectory that is more resilient
45 and fit for the future.

46
47 However, the transition towards a carbon-neutral world is complex and non-linear, and it will likely
48 result in some disruptions, with manifest equality implications, given the scale of the transformation
49 envisaged. There are parallel movements that can be observed. On the one hand, divestment initiatives
50 are underway to move away from carbon-intensive investments. On the other hand, hydrocarbon-rich
51 countries in some parts of the developing world are identifying new opportunities to reduce the fiscal
52 loss associated with the loss of fossil-fuel revenues. Indeed, with global investment in energy expected
53 to shrink by 20% this year, this has created fiscal challenges for countries that are heavily reliant on
54 fossil-fuel products as their main source of revenue.

1
2 Other disruptions are linked to redundant contracts and postponed or cancelled explorations, as many
3 oil companies are diversifying their production in the wake of the pandemic and are cutting back on
4 planned hydrocarbon investments (Denton et al, 2021). These failed concessions and disruptions have
5 implications for the just transition, especially in developing countries without the financial ability to
6 pull out of fossil fuels and to diversify with the same urgency as the industrialized nations (Peszko et
7 al. 2020). For instance, in South Africa, which is seeking to divest away from coal and decarbonize its
8 energy sector, if the transition is not properly managed, this could lead to a loss in revenue of R1.8
9 trillion (USD125 billion), thus compromising the government’s ability to support social spending
10 (Huxham et al. 2019). Emerging oil producers like Uganda are having to postpone the start of
11 production. Eni and Total, two of the largest international oil and gas majors in Africa, have already
12 signalled they are making 25% cuts to their investment in exploration and production projects in
13 2020, representing a €4bn reduction in foreign direct investment for Total and a USD2bn reduction for
14 Eni (Le Bec 2020).

15
16 A poorly managed transition will reproduce inequalities, thus contradicting the very essence of a just,
17 sustainable, inclusive transition. Revenues from oil and gas have been ploughed into social safety nets
18 and are supporting free senior high-school education in countries such as Ghana, thus enabling the
19 realisation of SDG 4 on quality education (UNU-INRA 2020). The move from fossil fuels towards a
20 low-carbon economy has economic implications for lower income countries that are dependent on
21 hydrocarbon resources, are endowed with significant untapped oil and gas reserves, and may not have
22 the transitional tools to move towards low-carbon technologies or economies (Peszko et al. 2020).

23
24 The energy transition landscape is changing rapidly, and we are witnessing multiple transitions. This
25 creates room to manage the transition in ways that will prioritise the need for workers in vulnerable
26 sectors (land, energy) to secure their jobs and to maintain a secure and healthy lifestyle, especially as
27 the risks multiply for those who are exposed to heavy industrial jobs and all the associated outcomes.
28 The shift to carbon neutrality is being driven by convergent factors related to energy security and the
29 benefits of climate mitigation, including the health impacts of air pollution and consumer demand
30 (Svobodova et al. 2020).

31
32 Climate change is high on the global agenda, as is energy’s role in decarbonizing the economy, giving
33 rise to a number of equality issues. Oswald et al. (2020) have shown that economic inequality translates
34 into inequality in energy consumption, as well as emissions. This is largely because people with
35 different levels of purchasing power make use of different goods and services, which are sustained by
36 different energy quantities and carriers (Oswald et al. 2020; Poblete-Cazenave et al. 2021)

37
38 A study by Bai et al. (2020) shows that an increase in income inequality in China hinders the carbon
39 abatement effect of innovations in renewable energy technologies, possibly even leading to an increase
40 in carbon emissions, while a decrease in inequality of incomes is conducive to giving play to the role
41 of this carbon abatement effect, thereby indicating that there is an important correlation between the
42 goals of “sustainable social development” and “sustainable ecological development”.

43
44 India is home to one sixth of world’s population but accounts for only 6.8% of global energy use and
45 consumes only 5.25% of electricity produced globally. During the period 1990–1991 to 2014–2015,
46 overall energy intensity in India declined from 0.007 Mtoe per billion INR of GDP to 0.004 Mtoe per
47 billion INR of GDP, an annual average decline of 2%. The industrial sector is making the highest
48 contribution CO₂ mitigation by reducing its energy intensity (Roy et al. 2021).

49
50 Household carbon emissions are mainly affected by incomes and other key demographic factors.
51 Understanding the contribution of these factors can inform climate responsibilities and potential
52 demand-side climate-mitigation strategies. A study by Feng et al. (2021) on inequalities in household
53 carbon the in USA shows that the per-capita carbon footprint (CF) of the highest income group (>200
54 thousand USD per year) with 32.3 tons is about 2.6 times the per-capita CF of the lowest income group
55 (<15 thousand USD) with 12.3 tons. Most contributors of high carbon footprints across income groups

1 in the US are heating, cooling and private transport, which reflects US settlement structures and
2 lifestyles, heavily reliant as they are on cars and living in large houses.

3
4 Studies by Jaccard et al. (2021) on energy in Europe shown a top-to-bottom decile ratio (90:10) of 7.2
5 for expenditure, 3.1 for net energy and 2.6 for carbon. Given such inequalities, these two targets can
6 only be met through the use of carbon capture and storage (CCS), large efficiency improvements and
7 an extremely low minimum final energy use of 28 GJ per adult equivalent. Assuming a more realistic
8 minimum energy use of about 55 GJ ae^{-1} and no CCS deployment, the 1.5°C target can only be achieved
9 at near full equality. The authors conclude that achieving both stated goals is an immense and widely
10 underestimated challenge, the successful management of which requires far greater room for manoeuvre
11 in monetary and fiscal terms than is reflected in the current European political discourse.

12
13 The ‘Just Transition’ concept has evolved over the years (Sweeney and Treat 2018) and is still
14 undergoing further evolution. It emphasizes the key principles of respect and dignity for vulnerable
15 groups, the creation of decent jobs, social protection, employment rights, fairness in energy access and
16 use, and social dialogue and democratic consultation with relevant stakeholders, whilst coping with the
17 effects of asset-stranding or the transition to green and clean economies. The concept has come under
18 increased scrutiny, with its protagonists emphasizing the need to focus on the equality of the transition,
19 not simply on its speed (Forsyth 2014). The emphasis on justice is also gaining in momentum, with a
20 growing recognition that the sustainability transition is about justice in the transition and not simply
21 about economics (Newell and Mulvaney 2013; Swilling, M. Annecke 2010; Williams and Doyon 2020).
22 Scholars are increasingly of the view that a transition involving low-carbon development should not
23 replace old forms of injustice with new ones (Setyowati 2021).

24
25 The economic implications of the transition will be felt by developing countries with high degrees of
26 dependence on hydrocarbon products as a revenue stream, as they are exposed to reduced fiscal
27 incomes, given the low demand for oil and low oil prices and the associated economic fallout of the
28 pandemic. This link with stranded assets is important, but it may be overlooked, as countries whose
29 assets are becoming stranded may not have the relevant resources, knowledge, autonomy or agency to
30 design a fresh orientation or decide on the transition. In addition, some developing countries are
31 dependent not only on fossil-fuel revenues, but also on foreign exchange earnings from exports. This
32 dependence comes into sharp focus when one considers that 30% of the Malaysian government’s
33 revenues are linked to petroleum products, and that Mozambique, by exploiting its newly discovered
34 natural-gas reserves, can earn seven times the country’s current GDP over a period of 25 years (Cronin
35 et al. 2021). Thus, any attempt to accelerate the transition to low-carbon development must take into
36 account foreign exchange, domestic revenue and employment generation, which are precisely what
37 ensure the attractiveness of fossil-fuel industries (Addison and Roe 2018).

38 Energy use and its deployment are sovereign matters. State responsibilities over the control and use of
39 natural resources concern both current and future generations (Carney 2016). Climate-change impacts
40 will disable the food, water and energy systems of the most vulnerable. Therefore, the resources
41 required to enable a just transition are predicated on good leadership and governance institutions that
42 will support quality and justice-based transitions. Beyond energy systems, changes to land systems can
43 benefit from sustainable land management in ways that will reduce the pressure on land for food and at
44 the same time support carbon storage. With land coming under increased pressure, land and forest
45 management are critical for carbon sequestration, as well as other ecosystem benefits. Extractive
46 processes have impacts on land, and often there are few if any redistributive benefits for communities
47 in regions where extraction takes place. In addition, extraction of strategic minerals such as cobalt,
48 copper and lithium have been linked to violence, human rights abuses and conflict (Cronin et al. 2021).

49 However, in the race to achieve carbon neutrality by 2050, some of the other priorities of the transition,
50 like climate-change adaptation and its inherent vulnerabilities, might become muted, given the urgency
51 to mitigate at all costs. Consequently, the transition imperative reduces the scope for local priority-
52 setting and ignores the additional risks faced by countries with the least capacity to adapt. Equally, the

1 ‘just transition’ is often seen through the prism of job losses and the attendant retooling and reskilling
2 imperatives necessary to re-dynamize local businesses, especially those that may fail as a result of mine
3 closures. It is equally important to consider current disparities in knowledge and capacity which could
4 maintain the existing inequalities in the global regional distribution of costs and benefits. One striking
5 example is the manufacturing of PV in India when compared to manufacturing PV in China. In China,
6 manufacturing costs are lower than in India, as are import tariffs (Behuria 2020). Similarly, a solar
7 industry might have greater development prospects in one region than another given existing regional
8 disparities in human capital, infrastructure, finance and technological development (Cronin et al. 2021).

9
10 Low-carbon transitions and equality implications will depend on local contexts, regional priorities, the
11 points of departure of different countries in the transition and the speed at which they will want to travel.
12 Hence, timing and scope are important elements that are associated more with a quality transition than
13 a race to the bottom. To date the debate has had some obvious blind spots, not least considerations of
14 power, politics and political economy (Denton et al, 2021). Certainly, the transition will create winners
15 and losers, as well as stakeholders that can frame their economic interests so as to determine the
16 orientation, pace, timing and scope of the transition.

17
18 The determination of a just transition is complex and not simply dependent on the allocation of
19 perceived risks or solutions, but rather on how risks and solutions are defined (Forsyth 2014). Acting
20 urgently to achieve environmental solutions or meet transition imperatives has certain risks given the
21 need to go beyond commonplace definitions of the just transition by emphasizing the distributive or
22 procedural aspects. The framing of policies to align with fast and low-cost mitigation without paying
23 sufficient attention to social and economic resilience creates its own potential risks and can enhance
24 social vulnerability rather than address it. The need to distribute climate-change solutions must not
25 delegitimise appropriate economic growth strategies, nor indeed create the additional risks of policy
26 imposition. Perceptions of justice with regard to environmental problems and solutions matter equally.
27 Hence, the types of transition pathway that are chosen may have equality implications. Mitigation at all
28 costs, if done “cheaply and crudely”, can create additional problems for social justice and inclusive
29 development (Forsyth 2014).

30
31 The assumption that the benefits of mitigation are enough to offset trade-offs with other policy
32 objectives can be questioned. If one accepts the argument that not all adaptation addresses vulnerability
33 concerns (Kjellén 2006), and that some adaptation strategies can heighten vulnerabilities if there are
34 flaws in their design and implementation, then the same logic applies, namely that not all mitigation is
35 necessarily beneficial. Hence the emphasis on the transition resulting from mitigation should be placed
36 not only on speed or cost effectiveness, but also on legitimacy of the actions, and whether the transition
37 is well designed or not. In short, justice is not always a shorthand for acting ethically, but rather a point
38 of reasoning on what is considered legitimate. Planning for the transition often discounts human rights
39 and social inclusivity that can occur as the result of a rapid transition. The emphasis should be placed
40 on the management of the transition rather than the speed – for instance, if in the rush to build new
41 hydropower energy sources implies that populations are displaced, then this constitutes a human rights
42 violation (Castro et al. 2016; Piggot et al. 2019).

43
44 Ambitious climate goals can increase the urgency of mitigation and accelerate the speed at which carbon
45 neutrality is achieved. However, if the transition is done with speed, then this will leave diversification
46 efforts stymied, particularly in developing countries that are highly dependent on fossil-fuel revenue
47 streams (UNEP/SEI 2020). Transition decisions and policies may also have far-reaching gendered
48 implications, as the closure of mines is often linked to several ancillary businesses impacts where men
49 are laid off and women may have to take on multiple jobs to compensate for the reduction in the
50 household’s income (Piggot et al. 2019; UNU-INRA 2020).

51
52 A just transition holds out the prospects for alternative high-quality jobs, public-health improvements
53 and an opportunity to focus on well-being and prosperity, with spill-over benefits to urban areas and
54 economic systems. Nonetheless, countries that transition from fossil fuels experience different

1 challenges, different levels of dependence and have different capacities to transition. There will be
2 countries with lower capacity and higher dependence, and vice versa (UNEP/SEI 2020).

3
4 Deciding on matters of justice is essential to the transition, and there are several inherent questions to
5 consider when thinking through the allocation of costs and benefits, as is the case with distributive
6 justice. How matters are defined and who defines matters such as the timing of phasing out, prioritising
7 which energy sources need to be phased out and who might be affected are all political economy
8 questions (Piggot et al. 2019).

9
10 Similarly, when considering issues of procedural justice, there are matters related to interests,
11 participation and power dynamics that are essential to the process, but that might also subvert the
12 process, depending on whose rights, whose participation and whose power are being put in
13 jeopardy.(Forsyth 2014; Piggot et al. 2019). Hence, both distribution and procedure matter, as do inter-
14 generational and intra-generational equity in planning transitions. Six critical variables can shape or
15 inhibit the transition process. These are dependence, timing, capacity, agency, scope and inclusion
16 (Denton et al, 2021).

17
18 **Dependence**, or the extent to which a country may depend on revenue streams from fossil fuels, will
19 determine their ability to manage the transition from fossil fuels. Countries who rely on the proceeds
20 from hydrocarbon resources as economic rents to support fiscal income and spending on public service-
21 related needs such as education, health and infrastructure, export earnings and foreign exchange
22 reserves will have greater difficulties in foregoing their fossil-fuel resources.

23
24 **Timing**: the transition pathway has to be aligned with a timetable which is anchored in national
25 development priorities. For example, South Africa’s Integrated Resource Planning indicates that the
26 transition away from coal, if not aligned with national development priorities, will reproduce new forms
27 of inequality. In addition, if the transition is imposed and its timing is not organic, then this might also
28 produce social inequalities.

29
30 **Capacity**: Transitions need to reflect spaces and planning. If knowledge about the transition pathway
31 is not adequately mastered or in place, this can disable the process or steer it in the wrong direction.
32 Capacity also relates to several attributes, including technical, governance, institutional, technologies,
33 economic resources to manage the transition. Poorer countries will have difficulties in managing all
34 these resources, as well as absorbing the costs associated with the transition (UNEP/SEI 2020).

35
36 **Agency**: transitions are inherently about the sovereign right to determine one’s orientation towards low-
37 carbon development. However, given the urgency to stick to the Paris Agreement and the new
38 conditionalities related to post-COVID stimulus packages, the absence of agency to deal with the
39 transition might jeopardize its flow, orientation and pace (Newell and Mulvaney 2013).

40
41 **Scope**: the extent to which the transition is rolled out and its potential impacts. If transition policies are
42 ambitious in making commensurate diversification investments, this may enable job creation, but it may
43 also affect employees who are insufficiently prepared to undertake new jobs and skills.

44
45 **Inclusion**. Who is considered in the transition process and how their interests and risks are assessed are
46 important aspects of transition pathways. Stakeholders with strong vested interests may resist the
47 transition, especially as it moves towards diversification activities and policies.

48 49 17.3.3 Cross-sectoral transitions

50 Transitions will involve multiple sectoral- and cross-sectoral policies. Section 17.3.3 presents a range
51 of studies and conclusions on the relationship between climate-change mitigation goals and meeting the
52 SDGs in order to identify major synergies and trade-offs. The interactions are manifold and complex
53 (Section 4.3.1.2 in Section 4; Nilsson et al. 2016; Pradhan et al. 2017). Here we draw on conclusions
54 from sectoral chapters and add additional studies as a basis for drawing more general conclusions about

1 agriculture, food and land-use, the water-energy-food nexus, industry, cities, infrastructure and
2 transportation, cross-sectoral digitalization, and mitigation and adaptation relations.

3 4 *17.3.3.1 Agriculture, Forestry and Other Land Uses (AFOLU)*

5 Sustainable development and mitigation policies are closely linked in the agriculture, food and land-
6 use sectors. We assess synergies and trade-offs between meeting the SDGs and reducing GHG
7 emissions within the sectors based on modelling studies and case studies illustrating how trade-offs
8 between SDG 2 (zero hunger, biomass for energy) and SDG 15 (life on land) can be addressed by cross-
9 sectoral mitigation options.

10 Chapter 7 emphasizes the high expectations on land to deliver mitigation, yet the pressures on land have
grown with population, dietary changes, the impacts of climate change and the conversion of
uncultivated land to agriculture and other land uses. Agriculture, Forestry and Other Land Uses
(AFOLU) are expected to play a vital role in the portfolio of mitigation options across all sectors. The
AFOLU sector is also the only one in which it is currently feasible to achieve carbon dioxide removal
(CDR) from the atmosphere, including A/R, improved forest management and soil carbon sequestration
(see Chapters 7 and 12). The AFOLU sector has a significant mitigation potential, with many scenarios
showing a shift to net negative CO₂ emissions during the 21st century. Total cumulative AFOLU CO₂
sequestration varies widely across scenarios, with as much as 415 GtCO₂ being sequestered between
2010 and 2100 in the most stringent mitigation scenarios. The largest share of net GHG emissions
reductions from AFOLU in both the 1.5°C and 2°C scenarios is from forestry-related measures, such
as afforestation, reforestation and reduced deforestation. Afforestation, reforestation and forest
management result in substantial carbon dioxide removal in many scenarios. CO₂ and CH₄ show larger
and more rapid declines than N₂O, an indication of the difficulties of reducing N₂O emissions in
agriculture (Chapter 3).

11 The Global Assessment on Biodiversity and Ecosystem Services Report (IPBES 2019, Chapter 5)
12 assessed the relationship between meeting the goals of the Paris Agreement and SDGs 2 (zero hunger),
13 7 (affordable and clean energy) and 15 (life on land). It concluded that a large expansion of the amount
14 of land used for bioenergy production would not be compatible with these SDGs. However, combining
15 bioenergy options with other mitigation options, like more efficient land management and the
16 restoration of nature, could contribute to welfare improvements and to accessing food and water.
17 Demand-side climate-mitigation measures, like energy-efficiency improvements, reduced meat
18 consumption and reduced food waste, were considered to be the most economically attractive and
19 efficient options in order to support low GHG emissions, food security and biodiversity objectives.
20 Implementing such options, however, can involve challenges in terms of lifestyle changes (IPBES
21 2019).

22
23 The potential joint contribution of food and land-use systems to sustainable development and climate
24 change has also been addressed in policy programmes by the UN, local governments and the private
25 sector. These programmes address options for pursuing sustainable development and climate change
26 jointly, such as agroforestry, agricultural intensification, better agriculture practices and avoided
27 deforestation. Griggs and Stafford-Smith (2013) assess production- and consumption-based methods of
28 achieving joint sustainability and climate-change mitigation in food systems, concluding that efficiency
29 improvements in agricultural production systems can provide large benefits. Given the expectations of
30 high levels of population growth and the strong increase in the demand for meat and dairy products,
31 there is also a need for the careful management of dietary changes, as well for those areas which could
32 be used most effectively for livestock and plant production.

33
34 Loss of biodiversity has been highlighted in several studies as a major trade-off of the low stabilization
35 scenarios (Prudhomme et al. 2020). A wide range of mitigation and adaptation responses – for example,
36 preserving natural ecosystems such as peatland, coastal lands and forests, reducing the competition for
37 land, fire management, soil management and most risk management options – have the potential to
38 make positive contributions to sustainable development, ecosystems services and other social goals
39

1 (McElwee et al. 2020). Smith et al. (2019a) also stressed that agricultural practices (e.g. improving
2 yields, agroforestry), forest conservation (e.g. afforestation, reforestation), soil carbon sequestration
3 (e.g. biochar addition to soils) and the removal of carbon dioxide (e.g. BECCS) could contribute to
4 climate-change mitigation (Smith et al. 2019a). However, there are also options that could improve
5 biodiversity if they were implemented jointly with climate-change mitigation in AFOLU. In their
6 study, (Leclère et al. 2020) show that increasing conservation management, restoring degraded land and
7 generalized landscape-level conservation planning could be positive for biodiversity. In general, the
8 ambitious conservation efforts and transformations of food systems are central to an effective post-2020
9 biodiversity strategy.

10
11 The IPCC Special Report on Climate Change and Land (IPCC 2019) emphasizes the need for
12 governance in order to avoid conflict between sustainable development and land-use management. It
13 states: "Measuring progress towards goals is important in decision-making and adaptive governance to
14 create common understanding and advance policy effectiveness". The report concludes that measurable
15 indicators are very useful in linking land-use policies, the NDCs and the SDGs.

16
17 One example of an area where special governance efforts have been called for is the protection of
18 forestry, ecosystem services and local livelihoods in a context of the large-scale deployment of high-
19 value crops like palm oil, short-term, high income-generating activities and sustainable development.
20 Serious challenges are already being seen within these areas according to (IPBES 2019).

21
22 Palm-oil is one example of a product with potentially major trade-offs between meeting the SDGs and
23 climate-change mitigation in the agriculture, forest and other land uses (AFOLU) sector. Currently the
24 area under oil palms is showing a tremendous increase, mostly in forest conversions to oil-palm
25 plantations (Austin et al. 2019; Gaveau et al. 2016; Schoneveld et al. 2019). The conversion of peat
26 swamp forest and mineral forest to oil palms will yield different amounts of CO₂. A study by Novita et
27 al. (2020) shows that the carbon stock of primary peat-swamp forest was 1,770 Mg C/ha compared to
28 a carbon stock of oil palm of 759 Mg C/ha. The study conducted by Guillaume et al. shows that the
29 carbon stock in mineral soils was 284 Mg C/ha compared to that in rain forest, which was 110.76 Mg
30 C/ha (Guillaume et al. 2018).

31
32 Restoring peatlands is one of the most promising strategies for achieving nature-based CDR (Girardin
33 et al. 2021; Seddon et al. 2021). A study by Novita et al. (2021) shows that significantly different CO₂
34 emissions for different land-use categories are influenced more by the water table depth and latitude
35 position for those locations relative to other observed parameters, such as bulk density, air temperature
36 and rainfall.

37
38 Given that the frequent peat-land fires in Indonesia were caused by land clearances in the replanting
39 season, multi-stakeholder collaboration between oil-palm plantations, local communities and local
40 governments over practices such zero burning when clearing land might be one of the most effective
41 ways to reduce the deforestation impact of oil palm (Jupesta et al. 2020). Behavioural changes as a
42 mitigation option have been suggested as a major factor in aligning sustainable development, climate
43 change and land management. In the absence of the policy intervention, the expansion of oil-palm
44 plantations has provided limited benefits to indigenous and Afro-descended communities. Even when
45 oil-palm expansion improves rural livelihoods, the benefits are unevenly distributed across the rural
46 population (Andrianto et al. 2019; Castellanos-Navarrete et al. 2021). In any case, while oil-palm
47 production can improve smallholders' livelihoods in certain circumstances, this sector offers limited
48 opportunities for agricultural labourers, especially woman (Castellanos-Navarrete et al. 2019).

49
50 Economy-wide mitigation costs can be effectively limited by lifestyle, technology and policy choices,
51 as well as benefit from synergies with the SDGs. Synergies come from the consumption side *by*
52 managing demand. For example, reducing food waste leads to resources being saved because water,
53 land-use, energy consumption and greenhouse gas emissions are all reduced (Chapter 3).

1 IPCC 6th AR Chapter 12 emphasized that diets high in plant protein and low in meat, in particular red
2 meat, are associated with lower GHG emissions. Emerging food-chain technologies such as microbial,
3 plant, or insect-based protein promise substantial reductions in direct GHG emissions from food
4 production. The full mitigation potential of such technologies can only be realised in low-GHG energy
5 systems.

6
7 Springmann et al. (2018) conclude that reductions in food waste could be a very important option for
8 reducing agricultural GHG emissions, the demand for agricultural land and water, and nitrogen and
9 phosphorous applications. In addition to the possibility to reduce food waste, their study analysed
10 several other options for reducing the environmental effects of the food system, including dietary
11 changes in the direction of healthier, more plant-based diets and improvements in technologies and
12 management. It was concluded that, relative to a baseline scenario for 2050, dietary changes in the
13 direction of healthier diets could reduce GHG emissions by 29% and 5–9% respectively in a dietary-
14 guideline scenario, and by 56% and 6–22% respectively in a more plant-based diet scenario. Demand-
15 side, service-oriented solutions vary between and within countries and regions, according to living
16 conditions and context. Avoiding food waste reduces GHG emissions substantially. Dietary shifts to
17 plant-based nutrition leads to healthier lives and reduce GHG emissions (Chapter 5.3).

18
19 A similar study also found a positive impact from zero food waste. The ‘no food waste’ scenario could
20 decrease global average food calorie availability by 120 kcal person⁻¹ d⁻¹ and protein availability by
21 4.6 g protein person⁻¹ d⁻¹ relative to their baseline levels, thus reducing required crop and livestock
22 production by 490 and 190 Mt respectively. This lower level of production reduces agricultural land
23 use by 57 Mha and thus mitigates the associated side effects on the environment. The lower levels of
24 production also reduce the requirements for fertilizers and water by 10 Mt and 110 km³ respectively,
25 and GHG emissions are reduced by 410 MtCO_{2e} yr⁻¹ relative to the 2030 baseline. Reducing food waste
26 can contribute to lessening the demand for food, feed and other resources such as water and nitrogen,
27 reducing the pressure on land and the environment while ending hunger (Hasegawa et al. 2019).

28
29 In 2007, Britain launched a nationwide initiative to reduce household food waste, which achieved a 21
30 percent reduction within five years (FAO 2019). The basis of this initiative was the “Love Food, Hate
31 Waste” radio, TV, print and online media campaign run by a non-profit organization, the Waste and
32 Resources Action Programme (WRAP). The campaign raised awareness among consumers about how
33 much food they waste, how it affects their household budgets and what they can do about it. This
34 initiative collaborated with food manufacturers and retailers to stimulate innovation, such as re-sealable
35 packaging, shared meal-planning and food-storage tips. The total implementation costs during the five-
36 year period were estimated at GBP 26 million, from which it was households that derived the most
37 benefit, estimated to be worth GBP 6.5 billion. Local authorities also realized a substantial GBP 86
38 million worth of savings in food-waste disposal costs. As for the private sector, the benefits took the
39 form of increased product shelf lives and reduced product loss. While households started to consume
40 more efficiently and companies may have experienced a decline in food sales, the latter also stated that
41 the non-financial benefits, such as strengthened consumer relationships, had offset the costs.

42
43 The Asia Pacific Economic Cooperation (APEC) group of countries has also created several types of
44 public–private partnership to tackle food waste and reduce losses. Most of these partnerships are
45 focused on food-waste recycling in both developed and developing countries (Rogelj et al. 2018). APEC
46 members stated that knowledge-sharing and improved policy and project management were the most
47 important advantages of public–private partnerships.

48
49 The inextricably intertwined factors in decision-making are influenced by the characteristics of the
50 person, in interaction with the characteristics of more sustainable practices and products, which interact
51 with a particular context that includes the immediate environment (e.g., household, farm), the indirect
52 environment (e.g., community) and macro-environmental factors (e.g., the political, financial and
53 economic contexts) (Hoek et al. 2021). Hence, to influence people to make decisions in favour of
54 sustainable food production or consumption, a wider perspective is needed on decision-making

1 processes and behavioural change, in which individuals are not targeted in isolation, but in interaction
2 with this wider systemic environment.
3

4 In conclusion, the AFOLU sector offers many low-cost mitigation options, which, however, can also
5 create trade-offs between land-use for food, energy, forest and biodiversity. Some options can help to
6 mitigate such trade-offs, like agricultural practices (e.g., improved yields, agroforestry), forest
7 conservation (e.g. afforestation, reforestation), soil carbon sequestration (e.g. biochar addition to soils)
8 and the removal of carbon dioxide (e.g. BECCS), which could contribute to climate change mitigation.
9 Lifestyle changes, including dietary changes and reduced food waste, are tightly embedded in modes
10 of behaviour that are influenced by the immediate environment (e.g., household, farm), the indirect
11 environment (e.g., community) and macro-environmental factors (e.g., political, financial and economic
12 contexts). Achieving zero-food waste could reduce the demands for land (SDG 15), water use (SDG 6)
13 and chemical fertilizers (SDG 9), leading to GHG emissions reductions (SDG 13) by encouraging
14 sustainable consumption and production practices (SDG 12).
15

16 *17.3.3.2 Water-Energy-Food-Nexus*

17 This section addresses the links between water, energy and food in the context of sustainable
18 development and the associated synergies and trade-offs, with links to related chapters. The focus
19 outline includes scoping and the relationship with the SDGs, general climate-change impacts on global
20 water resources, energy-system impacts and the relationship to renewables, enabling strategies, trade-
21 offs and cross-sectoral implications (see also Chapter 12), nexus-management tools and strategies, and
22 a box with examples from India and South Africa.
23

24 The continually increasing pressures on natural resources, such as land and water, due to the rising
25 demands from increases in population and living standards, which also require more energy, emphasises
26 the need to integrate sustainable planning and exploitation (Bleischwitz et al. 2018).

27 The water-energy-food nexus is at the epicentre of these challenges, which are of global relevance and
28 are the focus of policies and planning at all levels and sectors of the global society. The nexus between
29 water, energy and food (WEFN) (Zhang et al. 2018b) is tight and complex, and needs careful attention
30 and deciphering across spatio-temporal scales, sectors and interests to balance proper management and
31 trade-offs and to pursue sustainable development (Biggs et al. 2015; Dai et al. 2018; Hamiche et al.
32 2016). The WEFN touches upon the majority of the UN's SDGs, such as 2, 6-7 and 11-15 (Bleischwitz
33 et al. 2018), and deals with basic commodities, thus guaranteeing the basic livelihoods of the global
34 population.

35
36 The task of gaining an improved understanding of WEFN processes across disciplines such as the
37 natural sciences, economics, the social sciences and politics has been further exacerbated by climate
38 change, population growth and resource depletion. In light of the system of interlinkages involved, the
39 WEFN concept essentially also covers land (Ringler et al. 2013) and climate (Brouwer et al. 2018;
40 Sušnik et al. 2018) and can be further assessed in light of the relevant economic, ecological, social and
41 SDG aspects (Fan et al. 2019a). Fan et al. (2019b) specifically, SDGs 2 (food), 6 (water), (7) energy,
42 11 (cities) and 12 (production and consumption) are considered essential to the WEFN (Bleischwitz et
43 al. 2018). The nexus approach was introduced in the early 2010s, when it was argued that advantages
44 could be gained by adopting a nexus approach with regard to cross-sectoral and human–nature
45 dependencies and by taking externalities into account (Hoffmann 2011). Hence, within the nexus,
46 obvious trade-offs exist with competing interests, such as water availability versus food production.
47

48 Climate change is projected to impact on the distribution, magnitude and variability of global water
49 resources. A yearly increase in precipitation of 7% globally is expected by 2100 in a high-emissions
50 scenario (RCP 8.5), although with significant inter-model, inter-regional and inter-temporal differences
51 (Giorgi et al. 2019). Similarly, extreme events related to the water balance, such as droughts and
52 extreme precipitation, are projected to shift in the future (RCP4.5) towards 2100: for example, the
53 number of consecutive dry days is projected to increase in the Mediterranean region, southern Africa,
54 Australia and the Amazon (Chen et al. 2014). In impact terms, an increase of 20-30% in global water-

1 use is expected by 2050 due to the industrial and domestic demand for water. Already four billion
2 people experience severe water scarcity for at least one month per year (WWAP-UNESCO 2019).

3
4 Globally, climate change has been shown to cause increases of 4%, 8% and 10% in the share of
5 population being exposed to water scarcities under the 1.5°C, 2°C and 3°C scenarios for global warming
6 respectively (RCP8.5) (Koutroulis et al. 2019). At the same time, climate change is projected to cause
7 a general increase in extreme events and climate variability, placing a substantial burden on society and
8 the economy (Hall et al. 2014). Other than the human influence on the global hydro-climate, human
9 activities have been shown to surpass even the impact of climate change in low to moderate emission
10 scenarios of the water balance (Haddeland et al. 2014). Similar conclusions have been found by
11 (Destouni et al. 2013; Koutroulis et al. 2019).

12
13 An obvious consequence of the impact of climate change on future hydro-climatic patterns is the fact
14 that the energy system is projected to experience vast impacts through climate change (Fricko et al.
15 2016; Van Vliet et al. 2016a; van Vliet et al. 2016; Chapter 6). In the short run, where fossil-fuel sources
16 make up a significant share of the global energy grid, climate impacts related to water availability and
17 water temperatures will affect thermoelectric power generation, which relies mainly on water cooling
18 (Larsen and Drews 2019; Pan et al. 2018); water is also used for pollution and dust control, cleaning
19 etc. (Larsen et al. 2019). Currently, 98% of electricity generation relies on thermoelectric power (81%)
20 and hydropower (17%) (van Vliet et al. 2016).

21
22 Of these thermoelectric sources, the vast majority employ substantial amounts of water for cooling
23 purposes, although there is a trend currently towards implementing more hybrid or drier forms of
24 cooling (Larsen et al. 2019).

25
26 The renewable energy conversion technologies that are currently dominant globally and are projected
27 to remain so are less vulnerable to water deficiencies than fossil-based technologies, since no cooling
28 is used. These renewable energy conversion sources include, e.g., wind, solar PV and wave energy. The
29 implementation of such sources will, in the longer run, have the potential to reduce water usage by the
30 energy sector substantially (Lohrmann et al. 2019). Also, an increasing share of renewables within
31 desalination, as well as improved irrigation efficiencies, have been shown to potentially improve the
32 inter-sectorial WEFN water balance (Lohrmann et al. 2019). Also, an increasing share of renewables
33 on connection with desalination, as well as improved irrigation efficiencies, have been shown to
34 potentially improve the inter-sectorial WEFN water balance (Caldera and Breyer 2020). Some less
35 dominant renewable-energy technologies do use water for cooling, such as geothermal energy and solar
36 CSP, if wet cooling is employed. Despite the general detachment from water resources, wind and solar
37 PV, for example, are highly dependent on climate-change patterns, including variability depending on
38 future energy-storage capacities and on-/off-grid solutions (Schlott et al. 2018). Furthermore, regardless
39 of whether or not they are based on renewables, climate change will affect energy usage across sectors,
40 such as heating and cooling in the building stock. The energy systems in question need to be able to
41 handle variations and extremes in demand (Larsen et al. 2020).

42
43 For the 2080s compared to 1971-2000, an increase of 2.4% to 6.3% in the global gross hydropower
44 potential, from the hydrological side alone, is seen across all scenarios (van Vliet et al. 2016 and Chapter
45 6). Alongside the global increase in hydropower potential, the global mean water-discharge cooling
46 capacity, which also relates to water temperatures, experiences a decrease of 4.5% to 15% across the
47 scenarios. In very general and global terms, when combined, these changes support the shift towards
48 sources of renewable energy, including hydropower, in the energy mix. When it comes to ensuring
49 stability in the management of the electricity grid, hydro-climatological extremes have the potential to
50 pose vast difficulties in certain regions and/or seasons depending on the nature of the energy mix (Van
51 Vliet et al. 2016b). Van Vliet et al. (2016a) showed significant reductions in both thermoelectric and
52 hydropower electricity capacities, exemplified by the 2003 European drought, which resulted in
53 reductions of 4.7% and 6.6% respectively.

1 The energy sector is vulnerable to production losses caused mainly by heatwaves and droughts, whereas
2 coastal and fluvial floods are also responsible for a large relative share of the energy sector's
3 vulnerability, as assessed by (Forzieri et al. 2018) for Europe in 2100. In total, heatwaves and droughts
4 will be responsible for 94% of the damage costs to the European energy system compared to 40% today.
5 Similarly, (Craig et al. 2018) show that, despite potentially minor spatiotemporally aggregated
6 differences for various energy-system components, such as demand, thermoelectric power, wind etc.,
7 the aggregated impact of climate change across these components will cause a significant impact on the
8 energy system, as currently exemplified by the USA. In terms of investments and management, it is
9 important to unravel these cross-component relations in light of the projected nature of the future
10 climate.

11 In the ongoing transition towards renewable sources of energy (see also Chapters 3, 4 and 6), the impact
12 of the hydro-climate on energy production continues to be highly relevant (Jones and Warner 2016). As
13 the shares of thermoelectric energy production in the energy grid go down along with the introduction
14 of thermoelectric cooling technologies using smaller amounts of water, new energy sources and
15 technologies are being introduced, and existing sources scaled up. Of these, hydropower, wind and solar
16 energy are the key energy sources currently and will be in the near future, making up 2.5% and 1.8%
17 of the total global primary energy supply in 2017 respectively (IEA 2019). Wind and solar energy are
18 directly independent of water in themselves, but are dependent on atmospheric conditions related to
19 processes that also drive the water balance and circulation. Hydropower, on the other hand, is directly
20 influenced by and dependent on the supply of water, while at the same time being an essential counter-
21 component to seasonality and climatological variation, as well as to current and future demand curves
22 and diurnal variations, as against wind and solar energy (De Barbosa et al. 2017).

23
24 Furthermore, policy instruments in power-system management, here exemplified by hydropower in a
25 climate-change scenario, have been shown to enhance energy production during droughts (Gjorgiev and
26 Sansavini 2018). The significant influence of variation in the planning of renewable energy for the 21st
27 century has also been highlighted by (Bloomfield et al. 2016). At the same time, the integration of
28 renewables must account for lower thermoelectric efficiencies and capacities due to increases in
29 temperature (van Vliet et al. 2016), power-plant closures during extreme weather events due to a lack
30 of cooling capacity (Forzieri et al. 2018) and further efficiency reductions and penalties following the
31 implementation of CCS technologies in the effort to reach the GHG mitigation targets (Byers et al.
32 2015). However, more recent studies find more promising amounts of water being used for energy
33 conversion (IEAGHG 2020; Magneschi et al. 2017).

34
35 The extraction, distribution and wastewater processes of anthropogenic water-management systems
36 similarly use vast amounts of energy, making the proper management of water essential to reduce
37 energy usage and GHG emissions (Nair et al. 2014 and Chapter 11). One study reports that the water
38 sector accounts for 5% of total US GHG emissions (Rothausen and Conway 2011). Within the WEFN,
39 there is an obvious trade-off between water availability and food production, competing demands that
40 pose a risk to the supply of the basic commodities of food, energy and water in line with the SDGs
41 (Bleischwitz et al. 2018; Gao et al. 2019), all of which has the potential for inter-sectorial or inter-
42 regional conflicts (Froese and Schilling 2019). Currently, 24% of the global population live in regions
43 with constant water-scarce food production, and 19% experience occasional water scarcities (Kummu
44 et al. 2014). To counterbalance the demand for food and comestibles in regions that experience constant
45 or intermittent supplies, transportation is needed, which in itself requires suitable infrastructure, energy
46 supplies, a well-functioning trading environment and support policies. Of the 2.6 billion people who
47 experience constant or occasional water scarcities in food production, 55% rely on international trade,
48 21% on domestic trade and the remainder on water stocks (Kummu et al. 2014).

49
50 The relations between the influence of hydro-climatic variability, socio-economic conditions and
51 patterns of water scarcity have been addressed by (Veldkamp et al. 2015). A key finding of this study
52 was the ability of the hydro-climate and the socio-economy to interact, enforcing or attenuating each
53 other, though with the former acting as the key immediate driver, and the influence of the latter
54 emerging after six to ten years.

1
2 The trade-offs between competing demands have been investigated on a continental scale in the US
3 Great Plains, highlighting the influence of irrigation in mitigating reductions in crop yields (Zhang et
4 al. 2018b). Despite crop-yield reductions of 50% in dry years compared to wet years, a key conclusion
5 was that the irrigation should be counterbalanced against general water and energy savings within the
6 context of trade-offs. In East Asia, the WEFN has been quantified, highlighting obvious trade-offs
7 between economic growth, environmental issues and food security (White et al. 2018). This same study
8 also highlights the concept of a virtual WEFN that includes water embodied within products that are
9 traded and shipped. (Liu et al. 2019) find an urgent need for proper assessment methods, including of
10 trade within the WEFN, due to the significant resource allocations.

11
12 Within the WEFN, the implementation of policies to achieve low stabilisation targets is strongly linked
13 to sustainable development within the water sector with regard to water management and water
14 conservation, indicating that additional coherence in policies affecting the water, energy and food
15 sectors (among others) will be critical in achieving the SDGs (see also Chapter 7). Subsidized fertilizers,
16 energy and crops can drive unsustainable levels of water usage and pollution in agriculture. More than
17 half the world's population, roughly 4.3 billion people in 2016, live in areas where the demand for water
18 resources outstrips sustainable supplies for at least part of the year. Irrigated agriculture is already using
19 around 70% of the available freshwater, and the large seasonal variations in water supply and the needs
20 of different crops can create conflicts between water needs across sectors at different time scales (Wada
21 et al. 2016). However, as there is little potential for increasing irrigation or expanding cropland (Steffen
22 et al. 2015), gaps in food production gaps must be closed by increasing productivity and cropping
23 densities on currently harvested land by increasing either rain-fed yields or water-use efficiency
24 (Alexandratos and Bruinsma 2012).

25
26 It has been argued that applying an integrated approach to water-energy-climate-food resource
27 management and policy-making is highly beneficial in properly addressing the co-benefits and trade-
28 offs (Brouwer et al. 2018; Howells et al. 2013), accommodating the SDGs (Rasul 2016) and in general
29 assessing enabling strategies to improve resource efficiency (Dai et al. 2018). For an integrated
30 approach to analysing the WEFN, a number of modelling approaches, tools and frameworks have been
31 proposed (Brouwer et al. 2018; de Strasser et al. 2016; Gao et al. 2019; Larsen et al. 2019; Smajgl et al.
32 2016), often involving multi-objective calibration. Such tools enable decision-makers to evaluate the
33 optimal water-allocation and energy-saving solutions for the specific geography in question. As an
34 example, (Scott 2011) found the higher transportability of electricity, compared to water, pivotal in
35 water-energy adaptation solutions in the USA, while arguing for the additional coordination of water
36 and energy policies as a key instrument in balancing the trade-offs.

37
38 Common to all these integrated efforts is the challenge involved in making comparisons across studies
39 due to the combined complexities of assumptions, model codes, regions, variables, forcings etc. To
40 accommodate these challenges, (Larsen et al. 2019) suggest employing shared criteria and forcing data
41 to enable cross-model comparisons and uncertainty estimates, as also highlighted by (Brouwer et al.
42 2018). Other limitations in current WEFN research are partial system descriptions, the failure to address
43 uncertainties, system boundaries, and evaluation methods and metrics (Zhang et al. 2018b). The lack of
44 proper access to WEFN data and data quality has been highlighted by (D'Odorico et al. 2018; Larsen
45 et al. 2019). Furthermore, gaps have been identified between theory and end-user applications in the
46 lack of any focus on food nutritional values as opposed to calories alone, in the understanding of water
47 availability in relation to management practices, in integrating new energy technologies and in the
48 resulting environmental issues (D'Odorico et al. 2018).

49
50 Therefore, looking ahead, future fields of WEFN research should provide greater insights into all these
51 aspects. Holistic frameworks have been put forward to facilitate methods of WEFN management by
52 focusing on, for example, the geographical complexities with regard to transboundary challenges within
53 hydrological catchments (de Strasser et al. 2016), aligning policy incentives (Rasul 2016) and making
54 synergies and trade-offs in relation to WEFN SDG targets (Fader et al. 2018) etc. The roles of all levels
55 of government in optimal WEFN management are also highlighted in (Kurian 2017), especially with

1 regard to shaping the behaviour of individuals. Furthermore, (Kurian 2017) highlights the challenges
2 involved in science and policy communicating with one another and in the provision of optimal
3 instruments and guidelines. Engaging non-experts and end-users in scientific processes is seen as
4 essential to capturing previous failures and successes and to ensure that understanding the challenges is
5 updated to help shape the research questions.

6
7 Coordination of water use across different sectors and deltas is an important factor in sustainable water
8 management. Examples of instruments and policies that support this from India and Sub-Saharan Africa
9 in relation to the groundwater crisis are given below. India is the world's largest user of groundwater
10 for irrigation, which covers more than half of the country's total irrigated agricultural area, is
11 responsible for 70% of food production and supports more than 50% of the population (700 million
12 people) (see also Chapter 7). However, excessive extraction of groundwater is depleting aquifers across
13 the country, and falls in the water table have become pervasive. Improved water-use efficiency in
14 irrigated agriculture is being considered, both globally and in India, as a way of meeting future food
15 requirements with increasingly scarce water resources (Fishman et al. 2015).

16
17 The entirety of Sub-Saharan Africa has an undeveloped potential for groundwater exploitation, despite
18 the general perception of a global groundwater crisis, this being due to the absence of services to support
19 groundwater development (Cobbing 2020). It is estimated that most Sub-Saharan countries in Africa
20 utilize less than 5% of their national sustainable yields (Cobbing and Hiller 2019). The initial tool for
21 driving sustainable groundwater exploitation is a change in the narrative of a lack of resources in order
22 to stimulate increased agricultural production and increased fulfilment of the SDGs (Cobbing 2020).
23 Quantitative measures of actual groundwater vulnerability based on multiple indicators have been
24 calculated by, for example, (van Rooyen et al. 2020), showing that 20.4% of South Africa's current
25 water resources are highly vulnerable and are projected to worsen fifty years into the future.

26
27 Despite the positive perspectives regarding Sub-Saharan groundwater resources, the 2015-2017 water
28 crisis in South Africa, including in Cape Town, clearly predicts vulnerability to climate variability
29 (Carvalho Resende et al. 2019), which is predicted to increase. Serving as inspiration for the future
30 mitigation of water depletion, (Olivier and Xu 2019) suggest certain governance tools to improve the
31 diversification of water sources and the management of existing supplies.

32 **17.3.3.3 Industry**

33
34 Industrial transformation is a core component in achieving sustainable development. Across all
35 industrial sectors, the development and deployment of innovative technologies, business models and
36 policy approaches at scale will be essential in accelerating progress both with meeting the economic
37 and social development goals and with achieving low emissions. In this section, we assess the synergies
38 and trade-offs between mitigation options and the SDGs, with a specific focus on asking whether
39 economic growth and employment creation can work jointly with climate actions and other SDGs in
40 least developed and developing countries. Examples of synergies and trade-offs are provided based on
41 the conclusions of Chapter 9 on the building sector and Chapter 11 on industry. The potential for
42 greening industry is discussed in relation to eco-industrial parks, with examples from Ethiopia, China,
43 South Africa and Ghana.

44
45 Chapter 11 concludes that achieving net zero emissions from the industrial sector are possible. This will
46 require the provision of electricity free from greenhouse gas (GHG) emissions, including from other
47 energy carriers, increased electrification, low carbon feedstocks, and a combination of energy
48 efficiency, reduced demand for materials, a more circular economy, electrification and carbon capture,
49 use and storage (CCUS).

50
51 The potential co-benefits of mitigation options in industry has been mapped out in Chapter 11 in relation
52 to five categories of mitigation options: material efficiency and reductions in the demand for materials,
53 the circular economy and industrial waste, carbon capture utilization and storage, energy efficiency,
54 and electrification and fuel switching (Figure 11.15 in Chapter 11). In particular, the first two categories
55 of options are assessed as having several co-benefits for the SDGs, including SDGs 3, 5, 7, 8, 9 11, 12,

1 and 15. Some studies also point out the potential trade-offs in respect of employment and the costs of
2 cleaner production. The other options primarily impact on climate actions, decent work and
3 employment, and industry as such.

4
5 Okereke et al. (2019) offer important generic conclusions on green industrialisation and the transition
6 based on a study of socio-technical transition in Ethiopia. The importance of drivers for changes in
7 terms of clear policy goals and government support for green growth and climate policies, as well as
8 support from a strong culture of innovation, is emphasized. The study also identifies key barriers in
9 relation to stakeholder interactions, the availability of resources and the ongoing tensions between
10 ambitions for high economic growth and climate change. Green innovation in industry critically
11 depends on regulations. Gramkow and Anger-Kraavi (2018) have assessed the role of fiscal policies in
12 greening Brazilian industry based on an econometric analysis of 24 manufacturing sectors. They
13 conclude that instruments like low-cost finance for innovation and support to sustainable practices
14 effectively promote green innovation.

15
16 Luken (2019) have assessed the drivers, barriers and enablers for green industry in Sub-Saharan Africa,
17 concluding that major barriers exist related to material and input costs, as well as product requirements
18 in foreign markets, and that as a result there are trade-offs between economic and environmental
19 performance. Studies of ten countries are reviewed, and although they suffer from limited information,
20 they conclude similarly that further progress is being hindered by poor access to finance and weak
21 government regulation. (Greenberg and Rogerson 2014) They similarly conclude that the greening of
22 industry in South Africa is lagging behind due to economic barriers and weak governance, despite its
23 high priority in government planning and among international partners.

24
25 Ghana has launched a "One District One Factory" (1D1F) initiative, aimed at establishing at least one
26 factory or enterprise in each of Ghana's 216 districts as a means of creating economic growth poles to
27 accelerate the development of these areas and create jobs for the country's increasingly youthful
28 population. The policy aims to transform the structure of the economy from one dependent on the
29 production and export of raw materials to a value-added industrialized economy driven primarily by the
30 private sector (Yaw 2018). As has been pointed out by (Mensah et al. 2021), in its initial design the
31 programme did not take environmental quality into consideration. Although it was successful in creating
32 economic growth, exports and employment, the environmental impacts have been negative. It has
33 therefore been recommended that environmental regulations be imposed on foreign investments.
34 Similar conclusions have been drawn by (Solarin et al. 2017).

35
36 Chapter 11 concludes that eco-industrial parks, in which businesses cooperate with each other in order
37 to avoid environmental pressure and support sustainable development, have delivered several benefits
38 in relation to overall reductions in both virgin materials and final wastes, implying significant reductions
39 in industrial GHG emissions. Due to these advantages, eco-industrial parks have been actively
40 promoted, especially in East Asian countries such as China, Japan and South Korea, where national
41 indicators and governance exist (Geng et al. 2019; Geng and Hengxin 2009).

42
43 Zeng et al. (2020) have assessed the role of eco-industrial parks in China's green transformation for 33
44 development zones in relation to contributions to GDP, industrial value added, exports, water and
45 energy consumption, CO₂ levels and sulphur emissions. They concluded that industrial parks have
46 played a very important role in China's industrialisation, and that this structure has supported the
47 decoupling of economic growth and energy and water consumption from the environmental impacts.
48 However, improved environmental performance would require better access to finance and a higher
49 priority by management.

50
51 Eco-industrial parks have been promoted in Ethiopia by the government and UNIDO, based on the
52 expectation that they could help to boost the economy (UNIDO 2018, Oqubay et al 2021). One of the
53 success stories is an industrial park in Hawassa, a nation-level textile and garment industrial park with
54 a "zero emissions commitment" based on renewable energy and energy-efficient technologies.
55 However, the concept of the industrial park, including feasible policies and institutional arrangements,

1 is new to Ethiopia's regulatory processes, and this has created problems for management, knowledge
2 and governance, hindering their fast implementation.

3
4 A number of business associations have developed strategies for sustainable development and climate
5 change, including cooperate social responsibility (CSR). International initiatives have included the
6 promotion of CSR initiatives by international investors in low-income countries to support a broad
7 range of development priorities, including social working conditions, eliminating child labour and
8 climate change (Lamb et al. 2017). Leventon et al. (2015) evaluated the role of mining industries in
9 Zambia in supporting climate-compatible development and concluded that, although the industry has
10 played a positive role in avoiding migration and pressure on forest resources, there is a lack of
11 coordination between government and industry initiatives.

12
13 It can be concluded that most of the mitigation options in industry considered in this section could have
14 synergies with the SDGs, but also that some of the renewable-energy options could indicate some trade-
15 offs in relation to land use, with implications for food- and water security and costs. Carbon capture
16 and storage could play an enabling role in the provision of reliable, sustainable and modern energy and
17 could support decarbonisation, but it can also be costly (IEAGHG 2020; Mikunda et al. 2021). The
18 provision of water for CCS can include both synergies and trade-offs with the SDGs due to recent
19 progress in water-management technologies (Giannaris et al. 2020; IEAGHG 2020; Mikunda et al.
20 2021)

21 22 **17.3.3.4 Cities, Infrastructure and Transportation**

23 With 80% of the global population expected to be urban by 2050, cities will shape development paths
24 for the foreseeable future (United Nation 2018). The challenge for many policymakers is to construct
25 development paths that make cities clean, prosperous and liveable while mitigating climate change and
26 building resilience to heatwaves, flooding and other climate risks. The IPCC 1.5 report sees achieving
27 these objectives as feasible: cities could potentially realize significant climate and sustainable-
28 development benefits from shifting development paths (Wiktorowicz et al. 2018). The section assesses
29 the synergies and trade-offs between meeting the SDGs and climate-change mitigation, as well as
30 providing a general overview of mitigation options in cities and of enabling factors, including city
31 networks and plans for jointly addressing the SDGs and climate-change mitigation.

32
33 Chapter 8 concludes that urban areas potentially offer several joint benefits between mitigation and the
34 SDGs, and that since AR5, evidence of the co-benefits of urban mitigation continues to grow. In
35 developing countries, a co-benefits approach that frames climate objectives alongside other
36 development benefits arise increasingly being seen as an important concept justifying and driving
37 climate-change actions in developing countries (Sethi and Puppum De Oliveria 2018; Seto et al. 2016).

38
39 Evidence of the co-benefits of urban mitigation measures on human health has increased significantly
40 since the IPCC AR5, especially through the use of health-impact assessments in cities like Geneva,
41 where energy savings and cleaner energy-supply structures based on measures for urban planning,
42 heating and transport have reduced CO₂, NO_x and PM₁₀ emissions and increased the opportunities for
43 physical activity for the prevention of cardiovascular diseases (Diallo et al. 2016).

44 There is increasing evidence that climate-mitigation measures can lower health risks that are related to
45 energy poverty, especially in vulnerable groups, such as the elderly (Monforti-Ferrario et al. 2019).
46 Moreover, the use of urban forestry and green infrastructure as both a climate mitigation and an
47 adaptation measure can reduce heat stress (Kim and Coseo 2019; Privitera and La Rosa 2017) while
48 removing air pollutants to improve air quality (Scholz et al. 2018; De la Sota et al. 2019) and enhancing
49 well-being, including contributions to local development and possible reductions of inequalities (Lwasa
50 et al. 2015). Other studies evidence the potential to reduce premature mortality by up to 7,000 in 53
51 towns and cities and to create 93,000 net new jobs and lower global climate costs, as well as reduce
52 personal energy costs based on road maps for renewable energy transformations (Jacobson et al. 2018).

1 The co-benefits of energy-saving measures described by 146 signatories to a city climate network due
2 to improved air quality have been quantified as 6,596 avoided premature deaths (with a 95% confidence
3 interval of 4,356 to 8,572 avoided premature deaths) and 68,476 years of life saved (with a 95%
4 confidence interval of 45,403 and 89,358 years of life saved) (Monforti-Ferrario et al. 2019). Better air
5 quality further reinforces the health co-benefits of climate-mitigation measures based on walking and
6 bicycling, since the evidence suggests that increased physical activity in urban outdoor settings with
7 low levels of black carbon improves lung function (Laeremans et al. 2018). Chapter 9 shows that
8 mitigation actions in buildings have multiple co-benefits resulting in substantial social and economic
9 value beyond their direct impacts on reducing energy consumption and GHG emissions, thus
10 contributing to the achievement of almost all the United Nation’s SDGs. Most studies agree that the
11 value of these multiple benefits is greater than the value of the energy savings, while their quantification
12 and inclusion in decision-making processes will strengthen the adoption of ambitious reduction targets
13 and improve coordination across policy areas.

14
15 There are several examples of cities that have developed plans for meeting both the SDGs and
16 mitigation, which demonstrates the feasibility of meeting these objectives jointly. Quito, Ecuador, a city
17 with large carbon footprints (Global Opportunity Explorer 2019) and climate vulnerabilities, has
18 adopted low-carbon plans that aim to achieve the climate goals while introducing net zero energy
19 buildings and reducing water stress (Ordoñez et al. 2019; Marcotullio et al. 2018). Several cities in
20 China, Indonesia and Japan have invested in green city initiatives by means of green infrastructural
21 investments, which is claimed to be a form of smart investment. Through this type of investment,
22 economic growth and greenhouse gas (GHG) emissions reductions can be achieved in cities (Jupesta et
23 al. 2016). Multi-level governance arrangements, public-private cooperation and robust urban-data
24 platforms are among the factors enabling the pursuit of these objectives within countries (Corfee-Morlot
25 et al. 2009; Gordon 2015; Creutzig et al. 2019; Yarime 2017).

26
27 In addition to the mostly domestic enablers listed previously, some cities have also benefited from
28 working with international networks. The Global Covenant of Mayors for Climate and Energy
29 (Covenant of Mayors 2019), the World Mayors Council on Climate Change, ECLEI, C40, and UNDRR
30 (ECLEI 2019; C40 Cities 2019; UN- UNDRR 2019) have provided targeted support, disseminated
31 information and tools, and sponsored campaigns (Race to Zero) to motivate cities to embrace climate
32 and sustainability objectives. Despite this support, it should be stressed that most cities are in the early
33 stages of climate planning (Climate-Adapt 2019; Eisenack and Reckien 2013; Reckien et al. 2018).
34 Furthermore, in some cases city policymakers may fail to highlight the synergies and trade-offs between
35 climate and sustainable development or rebrand GHG-intensive practices as ‘sustainable’ in relevant
36 plans (Tozer 2018).

37 With regard to city networks, Chapter 8, Section 8.5 concluded that the importance of urban-scale
38 policies for sustainability has increasingly been recognized by international organizations and national
39 and regional governments. For example, in 2015, more than 150 national leaders adopted the UN’s
40 2030 Sustainable Development Agenda, including stand-alone SDG 11, “make cities and human
41 settlements inclusive, safe, resilient and sustainable” (United Nations 2015 p. 14). The following year,
42 170 countries agreed to the UN New Urban Agenda (NUA), a central part of which is recognizing the
43 importance of national urban policies (NUPs) as a key to achieving national economic, social and
44 environmental goals (United Nations 2015a, 2017). Similarly, the Sendai Framework for Disaster Risk
45 Reduction identifies the need to focus on unplanned and rapid urbanization to reduce exposure and
46 vulnerability to the risks of disasters (United Nations 2015b).

47
48 For many cities, a key to reorienting development paths will be investing in sustainable, low-carbon
49 infrastructure. Because infrastructure has a long lifetime and influences everything from lifestyle
50 choices to consumption patterns, decisions over an estimated USD90 trillion of infrastructure
51 investment (from now to 2030) will be critical in order to avoid becoming locked into unsustainable
52 paths (WRI 2016). This is particularly true in developing countries, where demands for new buildings,
53 roads, energy and waste-management systems are already surging. To some extent, policies that
54 accelerate building renovation rates, including voluntary programmes (Van der Heijden 2018), can

1 support transitions down more sustainable paths (Kuramochi et al. 2018). Factoring climate and
2 sustainable development considerations into policy tools that facilitate quantitative emission
3 performance standard (EPS) and the inclusion of climate and sustainable development benefits and risks
4 in infrastructure assessments or risk-adjusted returns on investments in development banks could also
5 prove useful (Rydge et al. 2015). Strong policy signals from the UNFCCC and from national climate
6 policies and strategies (including NDCs) could facilitate uptake of the relevant policies and the use of
7 these tools.

8
9 Infrastructural investments will also have wide-ranging implications for sustainable, low-carbon urban
10 development, namely transport and mobility. To some extent, decision-making frameworks such as
11 Avoid-Shift-Improve could help make these patterns low carbon and sustainable (Dalkmann and
12 Brannigan 2007; Wittneben et al. 2009). Mixed land-use planning and compact cities can not only help
13 avoid emissions or shift travellers into cleaner modes (Cervero 2009),), they can also improve air
14 quality, reduce commuting times, enhance energy security and improve connectivity (Pathak and
15 Shukla 2016; Zusman et al. 2011)

16 17 *17.3.3.5 Mitigation-adaptation relations*

18 The section will consider the links between mitigation and adaptation options in the context of
19 sustainable development and the associated synergies and trade-offs. Cross-cutting conclusions will be
20 drawn based on Chapter 3 and the sectoral chapters of AR6 WGIII and Chapter 18 of AR6 WGII. The
21 focus will be on the following sectors: agriculture, food and land use; water-energy-food; industry and
22 the circular economy; and urban areas.

23
24 IPCC, WG II, concludes that coherent and integrated policy-planning is needed in order to support
25 integrated climate change adaptation and mitigation policies and that this is a key component of climate-
26 resilient development pathways. Section 4.5.2 in Chapter 4 assesses development pathways and the
27 specific links between mitigation and adaptation, concluding that there can be co-benefits, and trade-
28 offs, where mitigation implies maladaptation. However, adaptation can also be a prerequisite for
29 mitigation. It is therefore concluded that making development pathways more sustainable can build the
30 capacity for both mitigation and adaptation.

31
32 Climate actions, including climate-change mitigation and adaptation, are highly scale-dependent, and
33 solutions are very context-specific. Especially in developing countries, a strong link exists between
34 sustainable development, vulnerability and climate risks, as limited economic, social and institutional
35 resources often result in low adaptive capacities and high vulnerability. Similarly, the limitations in
36 resources also constitute key elements weakening the capacity for climate-change mitigation (Jakob et
37 al. 2014). The change to climate-resilient societies requires transformational or systemic changes, which
38 also have important implications for the suite of available sustainable-development pathways (Kates
39 et al. 2012; Lemos et al. 2013). Thornton and Combetti (2017) point to the need for social-ecological
40 transformations to take place if synergies between mitigation and adaptation are to be captured, based
41 on the argument that incremental adaptation will not be sufficient when climate-change impacts can be
42 extreme or rapid and when deep decarbonization simultaneously involves social change (Chapter 18 in
43 AR6 WG II).

44
45 As discussed in AR6 WG II, Section 18.4 in Chapter 18, there are synergies and trade-offs between
46 adaptation and sustainable development, as well as between mitigation and sustainable development,
47 which is supported by comprehensive assessments such as that by (Dovie 2019; Sharifi 2020). Links
48 between mitigation and adaptation options are identified in Chapter 18 in AR6 WG II, such as expected
49 changes in energy demand due to climate change interacting with energy-system development and
50 mitigation options, changes to agricultural production practices to manage the risks of potential changes
51 in weather patterns affecting land-based emissions and mitigation strategies, or mitigation strategies
52 that place additional demands on resources and markets. This increases the pressures on and costs of
53 adaptation or ecosystem restoration linked to carbon sequestration and the benefits in terms of the
54 resilience of natural and managed ecosystems, but it also could restrict mitigation options and increase
55 costs. Chapter 3 of AR6 WG III similarly concludes that the connectedness and coherence of actions to

1 mitigate climate change could support the conservation and adaptation of ecosystems and meet the
2 sustainable development goals more widely.

3
4 Options to reduce agricultural demand (e.g., dietary change, reducing food waste) can have co-benefits
5 for adaptation through reductions in the demand for land and water (Smith et al. 2019b). For example,
6 Grubler et al. (2018) show that stringent climate-mitigation pathways without reliance on BECCS can
7 be achieved through efficiency improvements and reduced energy service and consumptions levels in
8 high-income countries.

9
10 Agriculture, food and land-use is the sector where most climate policy options can simultaneously
11 generate impacts on mitigation, adaptation and the SDGs (Locatelli et al. 2015; Kongsager et al. 2016).
12 Bryan et al. (2013) identified a range of synergies and trade-offs across adaptation, mitigation and the
13 SDGs in Kenya, given the diversity of its climatic and ecological conditions. Improved management of
14 soil fertility and improved livestock-feeding practices could provide benefits to both climate-change
15 mitigation and adaptation, as well as increase income generation from farming. However, other
16 improvements to agricultural management in Kenya, for example, soil water conservation, could only
17 provide benefits across all three domains in some specific sub-regions.

18
19 Conservation agriculture can yield mitigation co-benefits through improved fertiliser use or the efficient
20 use of machinery and fossil fuels (Cui et al. 2019; Harvey et al. 2014; Pradhan et al. 2018). Climate-
21 smart agriculture (CSA) ties mitigation to adaptation through its three pillars of increased productivity,
22 mitigation and adaptation (Lipper et al. 2014), although managing trade-offs among the three pillars
23 requires care (Kongsager et al. 2016; Thornton and Comberti 2017; Soussana et al. 2019). Sustainable
24 intensification also complements CSA (Campbell et al. 2014). Enhanced sustainable adaption can lead
25 to effective emission-reduction benefits, such as climate-smart agricultural technologies (Nefzaoui et
26 al. 2012; Poudel 2014) and ecosystem-based adaptation. Berry, P et al. (2015); Geneletti and Zardo
27 (2016); and Warmenbol and Smith (2018) have shown how increases in livelihoods can contribute to
28 climate change mitigation in Europe.

29
30 Agroforestry can sustain or increase food production in some systems and increase farmers' resilience
31 to climate change (Jones et al. 2013). Some sustainable agricultural practices have trade-offs, and their
32 implementation can have negative effects on adaptation or other ecosystem services. Agricultural
33 practices can aid both mitigation and adaptation on the ground, but yields may be lower, so there may
34 be a trade-off between resilience to climate change and efficiency. Interconnections within the global
35 agricultural system may also lead to deforestation elsewhere (Erb et al. 2016). Implementation of
36 sustainable agriculture can increase or decrease yields, depending on context (Pretty et al. 2006)
37 (Chapter 4).

38
39 Land-based mitigation and adaptation will not only help reduce greenhouse gas emissions in the
40 AFOLU sector, but also help augment the sector's role as a carbon sink by increasing forest and tree
41 cover through afforestation and agroforestry activities and other eco-system-based approaches. Some
42 of these options, however, can also have negative impacts on GHG emissions in the form of indirect
43 impacts on land use (for a more detailed discussion, see Chapter 7). If managed and regulated
44 appropriately, the land use, land-use change and forestry (LULUCF) sector could play a key role in
45 mitigation and be a key sector for emissions reductions beyond 2025 instead of contributing
46 substantially to emissions reductions beyond 2025 (Keramidas et al. 2018). However, the large-scale
47 deployment of intensive bioenergy plantations, including monocultures, replacing natural forests and
48 subsistence farmlands are likely to have negative impacts on biodiversity and can threaten food and
49 water security, as well as local livelihoods, partly by intensifying social conflicts, partly by reducing
50 resilience (Díaz et al. 2019). Expansion on to abandoned or unused croplands and pastures nonetheless
51 present significant global potential, and will avoid the sustainability risks of expanding agriculture into
52 natural vegetation (Næss et al. 2021).

53
54 Based on a literature review, Berry et al. (2015) identified water-saving and irrigation techniques in
55 agriculture as attractive adaptation options that have positive synergies with mitigation in increasing

1 soil carbon, reducing energy consumption and reducing CH₄ emissions from intermittent rice-paddy
2 irrigation. These measures could, however, reduce water flows in rivers and adversely affect wetlands
3 and biodiversity. The study also concluded that afforestation could reduce peak water flows and increase
4 carbon sequestration, but trade-offs could emerge in relation to the increased demand for water.
5

6 Fast-growing tree monocultures or biofuel crops may enhance carbon stocks but reduce downstream
7 water availability and the availability of agricultural land (Harvey et al. 2014). Similarly, in some dry
8 environments, agroforestry can increase competition with crops and pastureland, decreasing
9 productivity and reducing the yields of catchment water (Schroback et al. 2011; Chapter 7).
10

11 Hydro-power dams are among the low-cost mitigation options, provided the cost of constructing the
12 plant is taken into account, but they could have serious trade-offs in relation to key sustainable-
13 development aspects, since in respect of water and land availability dams can have negative effects on
14 ecosystems and livelihoods, thereby implying increased vulnerabilities. Section 17.3.3.2 on the water-
15 energy-food nexus includes examples of trade-offs between the benefits of producing electricity from
16 hydro-power dams and the trade-offs with ecosystem services and using land for agriculture and
17 livelihoods.
18

19 There are several potentially strong links between climate-change adaptation in industry and climate-
20 change mitigation. Various supply chains can be affected by climate change, energy supply and water
21 supply, and other resources can be disrupted by climate events. Adaptation measures can influence
22 GHG emissions in their turn and thus mitigation because of the demand for basic materials, for example,
23 as well as by influencing outdoor environments and labour productivity (Chapter 11.1.4).
24

25 Implementing adaptation options in industry can also imply increasing the demand for packaging
26 materials such as plastics and for access to refrigeration. These are among the adaptation options that
27 are dependent on temperature and storage possibilities, as well as being major sources of GHG
28 emissions.
29

30 An increasing number of cities are becoming involved in voluntary actions and networks aimed at
31 drawing up integrated plans for sustainable development and climate-change mitigation and adaptation,
32 including cities in both high- and low-income countries around the world. Grafakos et al. (2019);
33 Sanchez Rodriguez et al. (2018) concluded that cities are an obvious place for the development of plans
34 that can capture several synergies between sustainable development and climate-resilient pathways.
35 Kim and Grafakos (2019); and Landauer et al. (2019) similarly concluded that cities are an obvious
36 platform for the development of integrated planning efforts because of the scale of policies and actions,
37 which could potentially match the different policy domains. Kim and Grafakos (2019) assessed the level
38 of integration of mitigation and adaptation in urban climate-change plans across 44 major Latin
39 American cities, concluding that the integration of climate-change mitigation and adaption plans was
40 very weak in about half the cities and that limited donor finance was a main barrier. The authors also
41 mention barriers in relation to governance and the weakness or lack of legal frameworks. The
42 integration of SDGs with adaptation could help increase the willingness of politicians to implement
43 climate actions, as well as provide stronger arguments for investing the required resources (Sanchez
44 Rodriguez et al. 2018).
45

46 The local integration of planning and policy implementation practices was also examined by Newell et
47 al. (2018) in a study of eleven Canadian communities. It was concluded that, in order to put plans into
48 practice, a deeper understanding needs to be established of the potential synergies and trade-offs
49 between sustainable development and climate-change mitigation and adaptation. A model was applied
50 to the evaluation of key impacts, including energy innovation, transportation, the greening of cities and
51 city life. The impact assessment came to the conclusion that multiple benefits, costs and conflicting
52 areas could be involved, and that bringing a broad range of stakeholders into policy implementation
53 was therefore to be recommended.
54

55 There are several links between mitigation and adaptation options in the building sector, as pointed out
56 in Chapter 9. Adaptation can increase energy consumption and associated GHG emissions (Kalvelage
57

1 et al. 2013; Campagnolo and Davide 2019), for example, in relation to the demand for energy to meet
2 indoor thermal comfort requirements in a future warmer climate (de Wilde and Coley 2012; Li and Yao
3 2012; Clarke et al. 2018). Mitigation alternatives using passive approaches may increase resilience to
4 the impacts of climate change on thermal comfort and could reduce cooling needs (Wan et al. 2012;
5 Andrić et al. 2019). However, climate change may reduce their effectiveness (Ürge-Vorsatz et al. 2014).

6
7 Mitigation and the co-benefits of adaptation in urban areas in relation to air quality, health, green jobs
8 and equality issues are dealt with in Section 8.2 in Chapter 8, where it is concluded that most mitigation
9 options will have positive impacts on adaptation, with the exception of compact cities, with trade-offs
10 between mitigation and adaptation. This is because decreasing urban sprawl can increase the risks of
11 flooding and heat stress. Detailed mapping between mitigation and adaptation in urban areas shows that
12 there are many, very close interactions between the two policy domains and that coordinated governance
13 across sectors is therefore called for.

14
15 Rebuilding and refurbishment after climate hazards can increase energy consumption and GHG
16 emissions in the construction and building materials sectors, as it could making the existing building
17 stock more climate-resilient (Hallegatte 2009; de Wilde and Coley 2012; Pyke et al. 2012) and thus also
18 support implementation of the Sendai framework on disaster risk reduction (United Nations 2015b).
19 Climate change in the form of extremely high temperatures, intense rainfall leading to flooding, more
20 intense winds and/or storms and sea level rises (SLRs) can seriously impact transport infrastructure,
21 including the operations and mobility of road, rail, shipping and aviation; Chapter 10 assesses the
22 impacts on subsectors within transportation. At the same time, these sectors are major targets for GHG
23 mitigation options, and many countries are currently examining what to do in terms of combined
24 mitigation-adaptation efforts, using the need to mitigate climate change through transport-related GHG
25 emissions reductions and pollutants as the basis for adaptation action (Thornbush et al. 2013; Wang and
26 Chen 2019). For example, urban sprawl indirectly affects climate processes, increasing emissions and
27 vulnerability, which worsens the ability to adapt (Congedo and Munafò 2014). Hence greater use of rail
28 by passengers and freight will reduce the pressures on the roads, while having less urban sprawl will
29 reduce the impacts on new infrastructure, often in more vulnerable areas (IPCC 2019; Newman et al.
30 2017).

31
32 Despite many links between mitigation and adaptation options, including synergies and trade-offs,
33 Chapter 13 concludes that there are few frameworks for integrated policy implementation. One review
34 of climate legislation in Europe found a lack of coordination between mitigation and adaptation, their
35 implementation varying according to different national circumstances (Nachmany et al. 2015).

36
37 In developing and least developed countries, there are many examples of climate policies in the NDCs
38 that have been drawn up in the context of sustainable development and that cover both mitigation and
39 adaptation (Chapter 13; Beg 2002; and Duguma et al. 2014). However, there are many barriers to joint
40 policy implementation. Despite the emphasis on both mitigation and adaptation policies, there is very
41 limited literature on how to design and implement integrated policies (Di Gregorio et al. 2017; Shaw et
42 al. 2014). For example, the links within the water, energy and food nexus require coordination among
43 sectoral institutions and capacity-building in innovative frameworks linking science, practice and policy
44 at multiple levels (Cook and Chu 2018; Nakano 2017; Shaw et al. 2014).

45
46 Another challenge is the shortage of financial, technical and human resources for implementing joint
47 adaptation and mitigation policies (Antwi-Agyei et al. 2018b; Chu 2018; David and Venkatachalam
48 2019; Kedia 2016; Satterthwaite 2017). Several studies have stressed that the lack of finance for
49 integrating policy implementation between sustainable development and climate-change mitigation and
50 adaptation may constitute barriers to the implementation of adaptation projects to protect least-
51 developed countries with many vulnerabilities.

52
53 Locatelli et al. (2016) come to similar conclusions regarding finance based on interviews with
54 multilateral development banks, green funds and government organizations in respect of the agricultural
55 and forestry sectors. International climate finance has been totally dominated by mitigation projects.

1 Those who were interviewed were asked about their willingness to change this balance and to commit
2 more resources to projects that address both climate-change mitigation and adaptation. More than two-
3 thirds of those interviewed, however, raised concerns that integrated projects could be too complicated
4 and that a greater alignment of financial models across different policy domains could entail greater
5 financial risks. Another barrier mentioned in respect of finance was that mitigation projects were
6 primarily aimed at GHG emissions reductions, while adaptation projects had more national benefits and
7 were also more suitable for community development and promoting equality and fairness. In an
8 assessment of 201 projects in the forestry and agricultural sectors in the tropics Kongsager et al. (2016),
9 found that a majority of the projects contributed to both adaptation and mitigation or at least had the
10 potential to do so, despite the separation between these two objectives by international and national
11 institutions.

13 *17.3.3.6 Cross-sectoral digitalization*

14 In this section, the potential role of digitalization as a facilitator of a fast transition to sustainable
15 development and low emission pathways is assessed based on sectoral examples. The contributions of
16 digital technology could contribute to efficiency improvements, cross-sectoral coordination, including
17 new IT services, and decreasing resource use, implying several synergies with the SDGs, as well as
18 trade-offs, for example, in relation to reduced employment, increasing energy demand and the
19 increasing demand for services, possibly increasing GHG emissions.

21 The COVID-19 pandemic caused radical temporary breaks with past energy use trends. How post-
22 pandemic recovery will impact on the longer-term energy transition is unclear. Recovering from the
23 pandemic with energy-efficient practices embedded in new patterns of travel, work, consumption and
24 production reduces climate mitigation challenges (Kikstra et al. 2021). The potential of digital contact-
25 tracing to slow the spread of a virus had been quietly explored for over a decade before the COVID-19
26 pandemic thrust the technology into the spotlight (Cebrian 2021). The COVID-19 crisis is among the
27 most disruptive events in recent decades and has had consequences for consumer behaviour. During the
28 lockdowns in most countries, consumers have turned to online shopping for food products, personal
29 hygiene and disinfection (Cruz-Cárdenas et al. 2021), making society more digitally literate.

31 The cost of new services provided by digitalization can be high, and this could imply barriers for low-
32 income countries in joining new global information sharing systems and markets. Altogether this
33 implies that any assessment of the contribution of digitalization to support the SDGs and low-carbon
34 pathways will only be able to provide very context-specific results. Digital technologies could
35 potentially disrupt production processes in nearly every sector of the economy. However, as an
36 emerging area experiencing the rapid penetration of many sectors, there could be a window of
37 opportunity for integrating sustainable development and low emission pathways. IIASA (2020)
38 concludes that the digital revolution is characterised by many innovative technologies, which can create
39 both synergies and trade-offs with the SDGs (IIASA 2020).

41 Digital technologies could potentially disrupt production processes in nearly every sector of the
42 economy. However, as an emerging area experiencing the rapid penetration of many sectors, there could
43 be a window of opportunity for integrating sustainable development and low emission pathways.
44 TWI2050 (2020) concludes that the digital revolution is characterised by many innovative technologies,
45 which can create both synergies and trade-offs with the SDG's (IIASA 2020).

47 WBSD (2019) has assessed the potential of communication technologies (ICT) to contribute to the
48 transition to a global low-carbon economy in the energy, transportation, building, industry, and other
49 sectors. The potential is estimated to be around 15% CO₂-equivalent emissions reductions in 2020
50 compared with a business as usual scenario. A range of ICT solutions have been highlighted, including
51 smart motors and industrial process-management in industry, traffic-flow management, efficient
52 engines for transport, smart logistics and smart energy systems.

1 The TWI2050 2019 report (IIASA 2019) assessed both the positive and negative impacts of
2 digitalization in the context of sustainable development. It found that efficiency improvements, reduced
3 resource-consumption and new services can support the SDGs, but also that there were challenges,
4 including in relation to equality, facing the least developed and developing countries because of their
5 low level of access to technologies. The necessary preconditions for successful digital transformation
6 include prosperity, social inclusion, environmental sustainability, protection of jobs and good
7 governance of sustainability transitions. One negative impact of digitalisation could be the rebound
8 effects, where easier access to services could increase demand and with it GHG emissions.
9 Digitalization in the manufacturing sector could also provide a comparative advantage to developed
10 countries due to the falling importance of labour costs, while the barriers to emerging economies
11 seeking to enter global markets could accordingly be increased.
12

13 In respect of governance, Krishnan et al. (2020) point out that the creation of synergies between
14 sustainable development and low-emission urbanization based on digitalization could face barriers in
15 the form of inadequate knowledge of structures and value creation through ecosystems that would need
16 to be addressed by means of smart digitalizing, requiring organizational measures to support
17 transformation processes.
18

19 Urban areas are one of the main arenas for new digital solutions due to rapid urbanization rates and high
20 concentrations of settlements, businesses and supply systems, which offer great potential for large-scale
21 digital systems. The emergence of smart cities has supported the uptake of smart integrated energy,
22 transportation, water and waste-management systems, while synergies have been created in terms of
23 more flexible and efficient systems. In its 2018 Policy and Action document, the Japanese Business
24 Federation (Keidanren) launched Society 5.0, which include plans for smart city development (Carraz
25 and Yuko 2019; Narvaez Rojas et al. 2021). To achieve smart cities, Society 5.0 aimed to facilitate
26 diverse lifestyles and business success, while the quality of life offered by these options will be
27 enhanced. It also aims to offer high-standard medical and educational services. Autonomous vehicles
28 will be available and integrated with smart grid systems in order to facilitate mobility and flexibility in
29 energy supply with a high share of renewable energy. The energy system will include microgrids,
30 renewable with demand-side controls aligned with local conditions.
31

32 Chapter 6 of this report on “Energy Systems” points out that there are many smart energy options with
33 the potential to support sustainable development by facilitating the integration of high shares of
34 fluctuating renewable energy in electricity systems, potentially storing energy in EV batteries or fuel
35 cells, and applying load shifting by varying prices over time. It is concluded that very large efficiency
36 gains are expected to emerge from digitalization in the energy sector (Figure 6.18 in Chapter 6).
37

38 Section 9.9.2 in Chapter 9 concludes that the improved energy efficiency and falling costs in the
39 building sector that could result from digitalization could have rebound effects in increasing both energy
40 consumption and comfort levels. Increasing GHG emissions could be the result, but if low-income
41 consumers are given faster access to affordable energy, this could agree with the SDGs, making it
42 desirable to integrate policies targeting mitigation.
43

44 Section 10.1.2 in Chapter 10 discusses how the sharing economy, which, for example, could be
45 facilitated by ICT platforms, could influence both mitigation and the SDGs. On the one hand, sharing
46 has the potential to save transport emissions, especially if EVs are supplied with decarbonised grid
47 electricity. However, an increase in transport emissions could result from this if increasing demand and
48 higher comfort levels are facilitated, for example, by making access to EVs relatively easy compared
49 with mass transit. Another possible trade-off is that the supply of public transport services would be
50 limited to the elderly and other user groups.
51

52 Green innovation in agriculture is another emerging area in which digitalization is making huge
53 progress. From the perspective of water provision, weather data can be used to predict rain amounts so
54 that farmers can better manage the application of farm chemicals to minimize polluting aquifers and
55 surface water systems used for drinking water. Meanwhile, smart meters, onsite and remote sensors and

1 satellite data connected to mobile devices allow real-time monitoring of crop-water and optimal
2 irrigation requirements. On the supply side, remote tele-control systems and efficient irrigation
3 technologies enable farmers to control and optimize the quantity and timing of water applications, while
4 minimizing the energy-consumption trade-offs of pressurized irrigation in both rural and urban
5 agricultural contexts (Germer et al. 2011; Ruiz-Garcia et al. 2009).

6
7 Technology-driven precision agriculture, which combines geomorphology, satellite imagery, global
8 positioning and smart sensors, enables enormous increases in efficiency and productivity. Taken
9 together, these technologies provide farmers with a decision-support system in real time for the whole
10 farm. Arguably, the world could feed the projected rise in population without radical changes to current
11 agricultural practices if food waste can be minimized or eliminated. Digital technologies will contribute
12 to minimizing these losses through increased efficiencies in supply chains, better shipping and transit
13 systems, and improved refrigeration.

14
15 In conclusion, in most cases digitalization options may have both positive synergistic impacts on
16 mitigation and the SDGs and some negative trade-offs. Energy-sector options are assessed primarily as
17 having synergies, while some digitalisation options in transport could increase the demand for emission-
18 intensive modes of transport. Digital platforms for the sharing economy could have both positive and
19 negative impacts depending on the goods and services that are actually exchanged (see Cross Chapter
20 Box 6 in Chapter 7). Options related to agriculture and the energy-water-food nexus could help manage
21 resources more efficiently across sectors, which could create synergies. Digitalization can also raise a
22 number of ethical challenges according to (Clark et al. 2019). Wider public discussion of internet-based
23 activities was accordingly recommended, including topics such as the negotiation of online consent and
24 the use of data for which consent has not been obtained.

25 26 *17.3.3.7 Cross-sectoral overview of synergies and trade-offs between climate change mitigation and* 27 *the SDGs*

28 Based on a qualitative assessment in the sectoral chapters 6, 7, 8, 9, 10, and 11, Figure 17.1 below
29 provides an overview of the most likely links between sectoral mitigation options and SDGs in terms
30 of synergies and trade-offs. The general overview provided in the figure is supplemented by specific
31 sector by sector comments on how the synergies and trade-offs mapped depend on the scale of
32 implementation and the overall development context of places where the mitigation options are
33 implemented. For some mitigation options these scaling and context-specific issues imply that there can
34 be both synergies and trade-offs in relation to specific SDGs. In addition to the information provided in
35 Figure 17.1, supplementary material (Supplementary Material Table 17.1) includes the detailed
36 background material provided by the sectoral chapters in terms of qualitative information for each of
37 the synergies and trade-offs mapped.

38
39 The assessment of synergies and trade-offs presented in Figure 17.1 depends on the underlying literature
40 assessed by the sectoral chapters. In cases where no information about the links between specific
41 mitigation options and SDGs are indicated, this does not imply that there are no links, but rather that
42 the links have not been assessed by the literature.

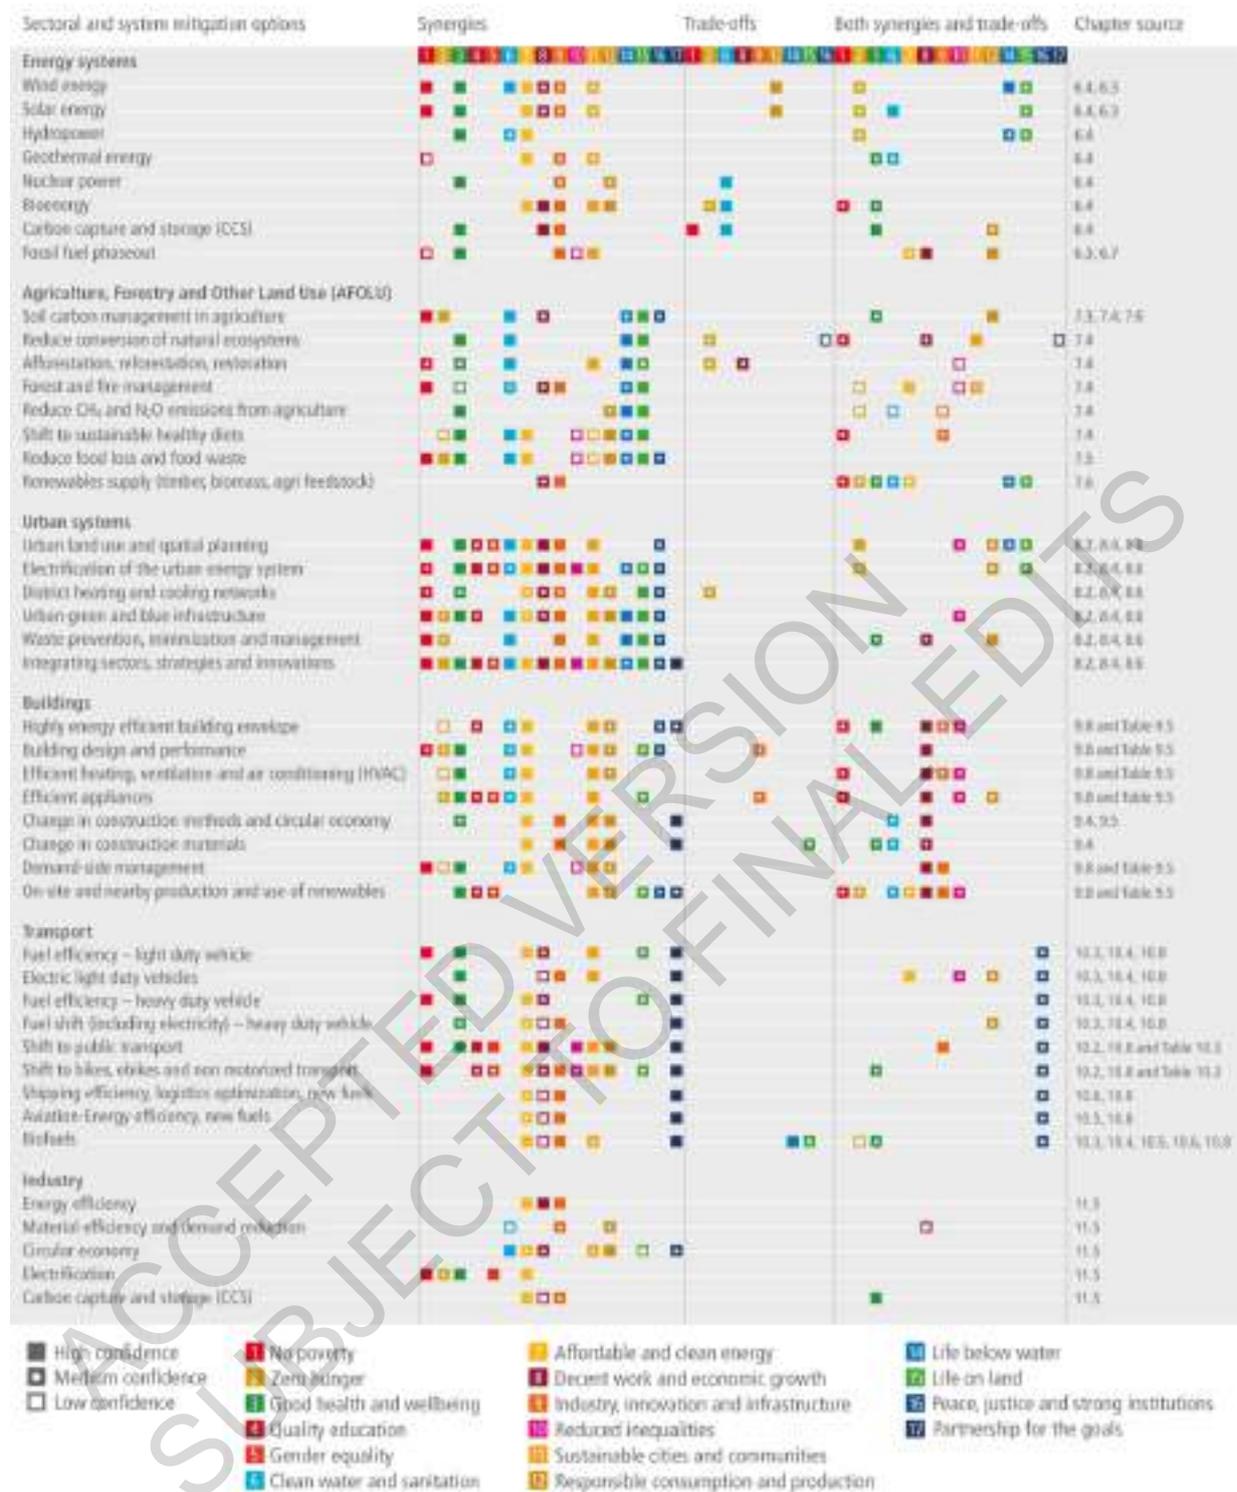

Figure 17.1 Trade-offs and synergies between sectoral mitigation options and the SDGs

1
2
3
4
5
6
7
8
9
10

Most of the energy sector options are assessed as having synergies with several SDGs, but there could be mixed synergies and trade-offs between SDG 2 ‘zero hunger’ for wind and solar energy, and for hydropower due to land-use conflicts and fishery damage. Offshore wind could also have both synergies and trade-offs with SDG 14 ‘life below water’ dependent on scale and implementation site, and it is emphasized that land-use should be coordinated with biodiversity concerns. Both wind and solar energy

1 are assessed as having trade-offs with SDG 12 ‘responsible production and consumption’ due to
2 significant material consumption and disposal needs.

3
4 Geothermal energy is assessed as having synergies with SDG 1 ‘zero poverty’ due to energy access and
5 mixed synergies and trade-offs in relation to SDG 3 ‘good health and well-being’ due to reduced air
6 pollution, but with some risks in relation to water pollution, and in relation to SDG 6 ‘clean water and
7 sanitation’, if it is not well managed. Nuclear power is assessed as having synergies with SDG 3 ‘good
8 health and well-being’ due to reduced air pollution, but potential trade-offs in relation to SDG 6 ‘clean
9 water and sanitation’ due to high water consumption, and water consumption issues are also possible in
10 relation to many of the other mitigation options in the energy sector. Synergies are identified in relation
11 to SDG 12 ‘responsible production and consumption’ for nuclear power due to low material
12 consumption. CCUS has been assessed as having trade-offs in relation SDG 1 ‘end poverty’ due to high
13 costs and SDG 6 ‘clean water and sanitation’ due to high water consumption. Synergies are related to
14 SDG3 ‘improved health and well-being’, and to SDG 9 ‘industry, innovation and infrastructure’ due to
15 the facilitation of decarbonisation of industrial processes. Both synergies and trade-offs could arrive in
16 relation to SDG 12 ‘responsible production and consumption’, since some rare chemicals and other
17 inputs could in some cases be used with large-scale applications.

18
19 Bioenergy use as a fuel is assessed as one of the energy-sector mitigation options with most synergies
20 and trade-offs with the SDGs. There could be synergies with SDG 1 ‘no poverty’, with SDG 8 ‘decent
21 work and economic growth’ and SDG 9 ‘industry, innovation and infrastructure’, This option, however,
22 if combined with CCS, can be expensive and can compromise SDG1 ‘end poverty’ due to the high costs
23 involved.

24
25 Agriculture, forestry and other land-use mitigation options are very closely linked to the SDGs and offer
26 both synergies and trade-offs, which in many cases are highly dependent on the scale of implementation.
27 All the mitigation options included in Figure 17.1 are assessed as potentially having synergies with
28 SDG 1 ‘end poverty’, but trade-offs could also happen if large areas are used for biocrops and taken
29 away from other activities, thus causing poverty, as well as in relation to food costs if healthier diets
30 are made more expensive. In relation to SDG 2 ‘zero hunger’, most of the mitigation options are
31 assessed as being associated with both synergies and trade-offs. Trade-offs are particularly a risk with
32 large-scale applications of afforestation projects, bioenergy crops and other land-hungry activities,
33 which can crowd out food production.

34
35 SDG ‘good health and well-being’ can be supported by many mitigation options in the agriculture,
36 forestry and food sectors, primarily due to the reduced environmental impacts, and the same is the case
37 with SDG 14 ‘life below water’ due to decreased nutrient loads, and SDG 15 ‘life on land’ due to
38 increased biodiversity, with the caveat however, that SDGs 14 and 15 could have both synergies and
39 trade-offs dependent on land use. It is considered that there could be both synergies and trade-offs in
40 relation to SDG 8 ‘decent work and economic growth’ due to competition over land use related to the
41 mitigation options reducing deforestation and reforestation and restoration, and the same is the case in
42 relation to SDG 7 ‘affordable and clean energy’ depending on the economic outcome of the mitigation
43 options. Similarly the mitigation option of reduced CH₄ and N₂O emissions from agriculture are
44 assessed as having mixed impacts on SDG 8 ‘decent work and economic growth’, and SDG 9 ‘industry,
45 innovation and infrastructure’ depending on innovative food production. The mitigation options of
46 reforestation and forest management are assessed as having mixed impacts on SDG 10 ‘reduced
47 inequalities’ depending on the involvement of local communities in projects. The assessment
48 emphasises that the synergies and trade-offs of the mitigation options with the SDGs in this sector are
49 very context- and scale-dependent, depending on how measures are carried out, for example, in relation
50 to the enhanced production of renewables needed to replace fossil fuel-based products. If done on a
51 massive scale and not adapted to local circumstances, there are adverse implications for food security,
52 livelihoods and biodiversity.

53
54 All the urban mitigation options that have been assessed are considered to have synergies with the
55 SDGs, and in a few cases both synergies and trade-offs are identified. In general, many links between

1 mitigation options in the urban area and the SDGs have been identified in the literature. Urban land-use
2 and spatial planning, for example, can support SDG1 ‘end poverty’, and can also reduce vulnerability
3 to climate change if integrated planning is undertaken, while access to food (SDG 2 ‘zero hunger’), and
4 water (SDG 6) can also be achieved if supported by integrated planning. Electrification, district heating,
5 and green and blue infrastructure in urban areas are expected to have synergies with all the SDGs
6 addressed by the reviewed studies.

7
8 Mitigation options like waste prevention minimization and management are also assessed as having
9 many synergies with the SDGs, but trade-offs could depend on the application of air-pollution control
10 technologies, and on the character of informal waste-recycling activities. The impacts of the possible
11 synergies and/or trade-offs with the SDGs will change according to the specific urban context.
12 Synergies and/or trade-offs may be more significant in certain contexts than others. Regarding the
13 SDGs, urban mitigation can support shifting pathways of urbanization towards sustainability. The
14 feasibility of urban mitigation options is also malleable and can increase with more enablers.
15 Strengthened institutional capacity that also supports the scale and coordination of the mitigation
16 options can increase the synergies between urban mitigation options and the SDGs.

17
18 As for the urban mitigation options, the reviewed buildings sector studies reveal a lot of links between
19 mitigation and the SDGs. Highly efficient building envelopes are expected to have synergies with the
20 SDGs in all cases except those with potential trade-offs in relation to SDG 10 ‘reduced inequalities in
21 relation to incomes’. Many SDG synergies are also identified for the building design and performance,
22 heating, ventilation and air conditioning, and efficient appliances mitigation options. However, some
23 trade-offs could appear in relation to SDG 8 ‘decent work and economic growth’ due to macroeconomic
24 impacts of reduced energy consumption, decreasing prices and stranded investments. Similar issues
25 related to the economic impacts of reduced energy demand are also highlighted for all the other
26 mitigation options, included for the building sector. In relation to construction materials and the circular
27 economy, some trade-offs have been identified in relation to SDG 6 ‘clean water and sanitation’ and
28 SDG 15 ‘life on land’ related to the use of biobased materials.

29
30 Consideration of the building sector highlights important context-specific issues related to synergies
31 and trade-offs between mitigation options and SDGs such as the economic impacts (synergies and trade-
32 offs) associated with reduced energy demand, resulting in lower energy prices, energy efficiency
33 investments, the fostering of innovation and improvements in labour productivity. Furthermore, the
34 distributional costs of some mitigation policies may hinder the implementation of these measures. In
35 this case, appropriate access policies should be designed to shield poor households efficiently from the
36 burden of carbon taxation. Under real-world conditions, improved cookstoves have shown smaller, and
37 in many cases limited, long-term health and environmental impacts than expected, as the households
38 use these stoves irregularly and inappropriately, and fail to maintain them, so that their usage declines
39 over time. Specific distributional issues are highlighted in relation to various cookstove programs.

40
41 The mitigation options in the transportation sector are assessed as having synergies with SDG 1 ‘no
42 poverty’ and SDG 3 ‘good health and well-being’ due to reduced environmental pollution, with
43 exceptions in relation to pollution from biofuels and the risks of traffic accidents. Trade-offs are also
44 mentioned in relation SDG 2 ‘zero hunger’ where the production of biofuels takes land away from food
45 production. Synergies are assessed in relation to SDG 7 ‘affordable and clean energy’, SDG 8 ‘decent
46 work and economic growth’ and SDG 9 ‘industry, innovation and infrastructure’. It is emphasized that
47 some mitigation options, like the increased penetration of electric vehicles, require innovative business
48 models, and that digitalization and automatic vehicles will support the socio-economic structures that
49 impede adoption of EV’s and the urban structures that enable reduced car dependence. In conclusion,
50 there is a need for investments in infrastructure that can support alternative fuels for LDVs. The large-
51 scale electrification of LDVs requires the expansion of low-carbon power systems, while charging or
52 battery-swapping infrastructure is needed for some segments.

53
54 The mitigation options in the industrial sector have been assessed primarily as having synergies with
55 meeting the SDGs. Several options, including energy efficiency, material recycling and electrification,

1 are assessed has being able to create increased employment and business opportunities related to SDG
2 8 ‘decent work and economic growth’, but material efficiency improvements could reduce tax revenues.
3 Electrification is assessed as having many synergies with SDGs, such as supporting SDG 1 ‘end
4 poverty’, SDG 2 ‘zero hunger’, and SDG 3 ‘good health and well-being’. CCS applied in industry is
5 assessed as having synergies in terms of the control of non-CO₂ pollutants (such as sulphur dioxide),
6 but increases in non-CO₂ pollutants (such as particulate matter, nitrogen oxide and ammonia). The
7 conclusion is that 15-25% additional energy will be required by CCS technologies compared with
8 conventional plants, implying that production costs could increase significantly. For the industrial sector
9 in general, it is concluded that the balance between synergies and trade-offs between mitigation options
10 and SDGs in industry depends on technology and the scale of the sharing of co-benefits across regions,
11 as well as on the sharing of benefits in business models over whole value chains.
12

13 Thus a number of cross-sectoral conclusions on synergies and trade-offs between mitigation options
14 and the SDGs appear from the overview provided in Figure 17.1. There are many synergies in all sectors
15 between mitigation options and the SDGs, and in a few cases there are also significant trade-offs that it
16 is very important to address, since they can compromise major SDGs including SDG1 ‘no poverty’,
17 SDG 2 ‘zero hunger’, and in some cases SDG 14 and SDG 15 ‘life below water’ and ‘life on land’. In
18 particular, mitigation options in relation to land-use, such as afforestation and reforestation and
19 bioenergy crops, can in some cases imply trade-offs with access to food and local sharing of benefits,
20 but synergies can also exist if proper land management and cross-sectoral policies take sustainable land-
21 use into account. The impacts and trade-offs for this sector are highly scale- and context-dependent, so
22 the final outcome of mitigation policies should be considered in detail.
23

24 The urban systems and transportation could potentially achieve many synergies between mitigation
25 policies and the SDGs, but integrated planning and infrastructure management are critical to avoiding
26 trade-offs. Similarly, the buildings sector and industry have identified many potential synergies between
27 mitigation options and the SDGs, but that raises issues related to the costs of new technologies, and in
28 relation to households and buildings important equity issues are emerging in relation to the ability of
29 low-income groups to afford the introduction of new technologies. Altogether these cross-sectoral
30 conclusions call for a need to support policies that aid coordination between different sectoral domains
31 and that include context-specific assessments of the sharing of benefits and costs related to the
32 implementation of mitigation options.
33
34

35 **17.4 Key barriers and enablers of the transition: synthesizing results**

36 This section provides a deep and broad synthesis of theory (section 17.2) and evidence (section 17.3)
37 in order to identify the conditions that either enable or inhibit transitions to sustainable low-carbon
38 futures. Following the literature on sustainability transitions (see Cross-chapter Box 12 on Transition
39 Dynamics), the section finds that there is rarely any one single factor promoting or preventing such
40 transitions. Rather, marked departures from business as usual typically involve several factors,
41 including technological innovations, shifts in markets, concerted efforts by scientists and civil-society
42 organizations to raise awareness of the costs of continued emissions, social movements, policies and
43 governance arrangements, and changes in belief systems and values.
44

45 All of this comes together in a co-evolutionary process that has unfolded globally, internationally and
46 locally over several decades (Hansen and Nygaard 2014; Rogge et al. 2017; Sorman et al. 2020), and
47 that may be guided or facilitated by interventions that target leverage points in the underlying
48 development path (Burch and Di Bella 2021; Leventon et al. 2021). While transitions necessarily follow
49 context-specific trajectories, more general lessons can be drawn by comparing the empirical details with
50 both system-level and narrower explanations of change.
51

52 Sections 17.2 and 17.3 show that transitions often face multiple barriers, including infrastructure lock-
53 in, behavioural, cultural and institutional inertia (Markard et al. 2020), trade-offs between transitions

1 and other social or political priorities (Chu 2016), cost and a reliable (and growing) supply of renewable
2 energy technologies and constituent materials (García-Olivares et al. 2018). Transitions away from
3 fossil fuels and toward renewable energy-based systems, for instance, will require significant land-use
4 decisions to avoid negative trade-offs with biodiversity and food security (Capellán-Pérez et al. 2017).
5 Previous sections underline a related need to move beyond focusing on “rational” assessments of the
6 costs and benefits of policies and technologies to involve people at all levels in order to overcome these
7 multiple barriers. For example, the case of coal-fired power in China (section 17.3) shows that a
8 transition to a lower carbon system is unlikely to happen even if models find it technically feasible and
9 cost-effective. Rather, achieving a transition requires breaking locked-in high-carbon technological
10 trajectories, path dependencies and resistance to change from the industries and actors that are
11 benefiting from the current system (Rogge et al. 2017). Lock-in effects may be weaker in sectors and
12 policy areas where fewer technologies exist, potentially opening the door to innovations that embed the
13 climate in broader sustainability objectives (e.g., technologies and innovations that support the
14 integration of food, water and energy goals). Such effects may still happen when there are significant
15 information asymmetries and high-cost barriers to action, as can occur when working across multiple
16 climate and development-related sectors (Kemp and Never 2017).
17

18 However, the same conditions that may serve to impede a transition (i.e., organizational structure,
19 behaviour, technological lock-in) can also be ‘flipped’ to enable it (Burch 2010; Lee et al. 2017), while
20 the framing of policies that are relevant to the sustainable development agenda can also create a stronger
21 basis and stronger policy support. The technological developments and broader cultural changes that
22 may generate new social demands on infrastructure to contribute to sustainable development will
23 involve a process of social learning and awareness building (Naber et al. 2017; Sengers et al. 2019).
24 However, it is also important to note that strong shocks to these systems, including accelerated climate-
25 change impacts, economic crises and political changes, may provide crucial openings for accelerated
26 transitions to sustainable systems through fundamental institutional changes (Broto et al. 2014). The
27 global COVID-19 pandemic is one such shock that has sparked widespread conversations about
28 recovery that is fundamentally more sustainable, equitable and resilient (McNeely and Munasinghe
29 2021). Key enabling conditions appear to be individual and collective actions, including leadership and
30 education; financial, material, social and technical drivers that foster innovation; robust national and
31 regional innovation systems that enhance technological diffusion (Wieczorek 2018); supportive policy
32 and governance dynamics at multiple levels that permit both agility and coherence (see e.g. Göpel et al.
33 2016); measures to recognize and address the challenges to equality inherent in the transition; and long-
34 range, holistic planning that explicitly seeks synergies between climate change and sustainable
35 development while avoiding trade-offs. The sections that follow seek to assess and integrate these key
36 categories of the barriers to and enablers of an accelerated transition to sustainable development
37 pathways.
38

39 **17.4.1 Behavioural and lifestyle changes**

40 Transitions toward more sustainable development pathways are both an individual and a collective
41 challenge, requiring an examination of the role of values, attitudes, beliefs and structures that shape
42 behaviour, and of the dynamics of social movements and education at the local community, regional
43 and global levels. Labelling the carbon included in products, for example, could help the decision-
44 making process and increase awareness and knowledge. Individual action suggests aggregated but
45 uncoordinated actions taken by individuals, whereas collective sustainability actions involve
46 coordination, a process of participation and governance that may ensure more efficient, equitable and
47 effective outcomes. There is evidence that the behaviour of individuals and households are part of a
48 more encompassing collective action (see also Chapter 5.4.1).
49

50 Indeed, individual actions are necessary but insufficient to deliver transformative mitigation, and it is
51 suggested that this be coupled with collective actions to accelerate the transition to sustainable
52 development (Dugast et al. 2019). Actors with conflicting interests will compete to frame mitigation
53 technologies that either “build or erode” the legitimacy of the technology, contested framing sites that
54 can occur between incumbent and emerging actors or between actors in new but competing spaces

1 (Rosenbloom et al. 2016). How narratives are built around desired development pathways and specific
2 emerging technologies, as well as how local values are integrated into visions of the future, have
3 relevance for how these experiments are managed and enabled to expand (Horcea-Milcu et al. 2020;
4 Lam et al. 2020).

6 **17.4.1.1 Social movements and education**

7 Sustainable development and deep decarbonization will involve people and communities being
8 connected locally through various means – including globally via the internet and digital technologies
9 (Bradbury 2015; Scharmer 2018; Scharmer, C, Kaufer 2015) –in ways that form social fields that allow
10 sustainability to unfold (see also Gillard et al. 2016) and that prompt other shifts in thinking and
11 behaviour that are consistent with the 1.5°C goal (O’Brien 2018; Veciana and Ottmar 2018). Indeed,
12 social movements serve to develop collective identities, foster collective learning and accelerate
13 collective action ranging from energy justice (see Section 17.4.5) (Campos and Marín-González 2020)
14 to restricting fossil-fuel extraction and supply (Piggot 2018). This does not apply only to adults: as seen
15 in the “Fridays for Future” marches, the young are also involving themselves politically (Peterson et al.
16 2019). Many initiatives have started with these marches, including “science for future” and new forms
17 of sustainability science (Shrivastava et al. 2020).

18
19 It was Theory-U (Scharmer 2018, building on the work of scholars like Schein, Lewin or Senge) that
20 inspired a so-called “massive open online course” (MOOC) jointly initiated by the Bhutan Happiness
21 Institute and German Technical Assistance (GIZ) in 2015, since when it has been developed further and
22 adapted to transform business, society and self as one example of how social movements can go together
23 with science and education. It brings together people from different professions, cultures and continents
24 in shared discussions and practices of sustainability. It also included marginalised communities and is
25 shifting towards more sustainable lifestyles in all sectors (Nikas et al. 2020), including climate action.

26
27 Moreover, approaches like the “Art of Hosting” (Sandfort and Quick 2015) and qualitative research
28 methods like storytelling and first-person research, as well as second-person inquiries, for example
29 (Scharmer, C, Kaufer 2015; Trullen and Torbert 2004; Varela 1999), have been employed to bridge
30 differences in cultures and sciences, as well as to forge connections between those working on climate
31 change and sustainable development. Likewise, experiential tools, simulations and role-playing games
32 have been shown to increase knowledge of the causes and consequences of climate change, the sense
33 of urgency around action and the desire to pursue further learning (Ahamer 2013; Eisenack and Reckien
34 2013; Hallinger et al. 2020; Rooney-Varga et al. 2020).

35
36 The results from these research communities reveal how experiential learning takes place and how it
37 encourages bonding between people, society and nature. This can be achieved by going jointly and
38 consciously into nature (Gioacchino 2019), by creating spaces for intensive dialogue sessions with
39 colleagues (Goldman-Schuyler et al. 2017) and forming, for example, a very practical u.lab hub, which
40 involves following the MIT-u.lab course with a local community and is accompanied scientifically
41 (Pomeroy and Oliver 2018). Others have pointed to social networks such as the “transition initiative”
42 (Hopkins 2010), eco-village networks (see e.g., Barani et al. 2018), civil-society movements (Seyfang
43 and Smith 2007) and intentional communities (see e.g., Grinde et al. 2018; Veciana and Ottmar 2018)
44 as ways of generating the shared understandings that are central to inner and outer transitions, as well
45 as the broader development of social movements. In some cases, these networks build on principles like
46 permaculture to encourage people to “observe and interact,” “produce no waste” and “design from
47 patterns to details”, not only in agriculture and gardening, but also in sustainable businesses and
48 technologies to reduce CO₂ emissions (see e.g., Ferguson and Lovell 2014; Lessem 2018).

49
50 A related line of inquiry involves education for sustainable development (ESD). This builds on the
51 UNESCO programme, ‘ESD for 2030’, and involves core values like peace culture, valuing cultural
52 diversity and living global citizenship. One of the core insights from research on ESC is lifelong
53 education continuing outside the classroom, a lifelong learning process that involves sustained actions
54 by all ages and social segments (see e.g., Hume and Barry 2015) and achieving collaboration (Munger
55 and Riemer 2012). Some authors have pointed to good levels of communication either directly or

1 through the internet as the key to facilitating this learning (Sandfort and Quick 2015). Others have noted
2 that transformative learning – that is, deepening the learning process – is critical because it helps to
3 induce both shared awareness and collective actions (see e.g., Brundiens et al. 2010; Singleton 2015;
4 Wamsler and Brink 2018).

5
6 A final area of work points to the importance of moving toward the knowledge production that
7 underpins awareness-raising (Pelling et al. 2015). The accumulation of applied knowledge is leading
8 increasingly to the co-design of participatory research with local stakeholders who are investigating and
9 transforming their own situations in line with climate action and sustainable development (see e.g.,
10 Abson et al. 2017; Fazey et al. 2018; Wiek et al. 2012).

11 **17.4.1.2 Habits, values and awareness**

12 Many of the cases that explore transitions to sustainable development point to engrained habits, values
13 and awareness levels as the most persistent yet least visible barriers to a transition. For example, in the
14 transport sector, individuals can quickly become accustomed to personal vehicles, making it difficult
15 for them to transition to sustainable, low-carbon modes of public transport. Demand for high-carbon
16 transportation may also be locked in, and habits reinforced, if low-cost housing (for instance) is not
17 sufficiently served by more sustainable (i.e. mass transit, safe cycling and walking infrastructure)
18 transportation options (Mattioli et al. 2020).

19
20
21 This is made all the more challenging because car-manufacturing “incumbents” utilize information
22 campaigns directed at the public, pursue lobbying and consulting with policy-makers, and set technical
23 standards that privilege the status quo and prevent the entry of more sustainable innovations (Smink et
24 al. 2015; Turnheim and Nykvist 2019). Tools such as congestion pricing, however, have been shown to
25 be effective in motivating the switch from single-occupancy vehicle use to public transit, thus
26 improving air quality and reducing traffic delays in dense city centres (Baghestani et al. 2020).

27
28 Complicating the problem further is that even well-intentioned top-down programmes initiated by an
29 external actor may in some cases ultimately hinder transformative change (Breukers et al. 2017). For
30 instance, in Delhi, India, attempts to introduce ostensibly more sustainable bus rapid transit (BRT)
31 systems failed in part due to an arguably top-down approach that had limited public support. It may
32 nonetheless be difficult to win public support (Bachus and Vanswijgenhoven 2018), and even grassroots
33 initiatives may themselves be contested and dynamic, making it difficult to generate the collective push
34 to drive a bottom-up transition forward (Hakansson 2018).

35
36 However, dominant, top-down approaches and local, grassroots “alternative” approaches and values do
37 overlap and interact. For example, in Manchester, UK, dominant and alternative discourses interact with
38 each other to create sustainable transformations through re-scaling (decentralizing) energy generation,
39 creating local engagement with sustainability, supporting green infrastructure to reduce costs, re-
40 claiming local land, transforming industrial infrastructure and creating examples of sustainable living
41 (Hodson et al. 2017).

42
43 Embedding local values in higher-level policy frameworks is also significant for forest communities in
44 Nepal and Uganda. Even so, policy intermediaries are not confident that these values will be advanced
45 due largely to an emphasis on carbon accounting and the distribution of benefits (Reckien et al. 2018).
46 In this case, however, norm entrepreneurs were able to promote the importance of local values through
47 the formation of grassroots associations, media campaigns and international support networks (Reckien
48 et al. 2018).

49 **17.4.2 Technological and social innovation**

50
51 Individuals and organizations, like institutional entrepreneurs, can function to build transformative
52 capacity through collective action (Brodnik and Brown 2018). The transition from a traditional water-
53 management system to the Water Sensitive Urban Design (WSUD) model in Melbourne offers an
54 illustration of how whole systems can be changed in an urban system.

1
2 Private-sector entrepreneurs also play an important role in fostering and accelerating transitions to
3 sustainable development (Burch et al. 2016; Ehnert et al. 2018a; Dale et al. 2017). Sustainable
4 entrepreneurs (SEs), for instance, are described as those who participate in the development of an
5 innovation while simultaneously being rooted in the incumbent energy-intensive system. SE actors who
6 have developed longer term relationships, both formal and informal, with the public authorities can
7 have considerable influence on developing novel renewable-energy technologies (Gasbarro et al. 2017).
8 Institutions and policies that nurture the activities of sustainable entrepreneurs, in particular small- and
9 medium-sized enterprises (Burch et al. 2016), can facilitate and strengthen transitions toward more
10 sustainable development pathways, as can more fundamental adjustments to underlying business
11 models, rather than relying only on incremental adjustments in the efficiency with which resources are
12 used (Burch and Di Bella 2021).

13
14 The creation and growth of sustainable energy and clean-tech clusters enable economic development
15 and transformation on regional scales. Such clusters can put pressure on incumbent technologies and
16 rules to accelerate energy transitions. Successful clusters are nurtured by multi-institutional and multi-
17 stakeholder actors building institutional support networks, facilitating collaboration between sectors
18 and actors, and promoting learning and social change. Notably, regional economic clusters generate a
19 buzz, which can have a strong influence on public acceptance, support and enthusiasm for
20 sociotechnical transitions (McCauley and Stephens 2012).

21
22 In Norway, many incumbent energy firms have already expanded their operations into the alternative
23 energy sector as both producers and suppliers (who often follow the lead of producers). Producers are
24 responding to perceptions of larger-scale changes in the energy landscape (e.g., the green shift), along
25 with uncertainties in their own sectors, and innovation can spill across actors in multiple sectors
26 (Koasidis et al. 2020). While these firms are expanding out of self-interest, the expansion provides more
27 legitimacy to new forms of technology and enables transfers of knowledge and resources to be
28 introduced within this developing niche (Steen and Weaver 2017). Many large, well-established firms
29 are pursuing sustainability agendas and opting for transparency with regard to their greenhouse gas
30 emissions (Guenther et al. 2016; Kolk et al. 2008), supply chain management (Formentini and Taticchi
31 2016) and sustainable technology or service development (Dangelico et al. 2016).

32
33 Experiments with the transition open up pathways that can lead to energy transitions on broader scales.
34 Experiments can build capacity by developing networks and building bridges between diverse actors,
35 leveraging capital from government funds, de-risking private- and public-sector investment, and acting
36 as hubs for public education and engagement (Rosenbloom et al. 2018).

37
38 Material barriers and spatial dynamics (Coenen et al. 2012; Hansen and Coenen 2015) are other critical
39 obstacles to innovation: often, infrastructure and built environments change more slowly than policies
40 and institutions due to the inherently long lifespans of fixed assets (Turnheim and Nykvist 2019). The
41 example of transport infrastructure in Ontario, Canada, illustrates the need to integrate climate change
42 into these infrastructural decisions in the very short term to combat the risk of being left with
43 unsustainable planning features long into the future, especially combustion engines, significant road
44 networks and suburbanization (Birch 2016).

45 46 **17.4.3 Financial systems and economic instruments**

47 Market-oriented policies, such as carbon taxes and green finance, can promote low-carbon technology
48 and encourage both private and public investment in enabling transitions. Policies that are currently
49 being tested include loan guarantees for renewable energy investments in Mali, policy insurance to
50 reduce credit defaults within the feed-in tariff regime in Germany, or pledged funding to fully finance
51 or partner private firms in order to advance renewable energy projects (Roy et al. 2018a). However,
52 there may be some limitations in using carbon-pricing alone (rather than in combination with flexible
53 regulations and incentives) where market failures hinder low-carbon investments (Campiglio 2016;
54 World Bank 2019) and high political costs are incurred (Van Der Ploeg 2011).

1
2 Many forms of transformational change to energy systems are not possible when financial systems still
3 privilege investing in unsustainable, carbon-intensive sectors. One of the root causes of the failure of
4 traditional financial systems is the undervaluation of natural capital and unsettled property right issues
5 that are associated with it. The exclusion of proper rents for scarcities or for global and local
6 externalities, including climate change, can undermine larger-scale changes to energy systems (Clark
7 et al. 2018). But even smaller-scale low-carbon energy and infrastructure projects can fail to get off the
8 ground if uncertainty and investment risk discourage project planning and bank-lending programmes
9 (Bolton et al. 2016). The EU's previous actions regarding the "shareholder maximisation norm" and
10 non-binding measures have created path dependencies, limiting its flexibility in creating sustainable
11 financial legislation. However, the Sustainable Finance Initiative and the Single Market may prove to
12 be "policy hotspots" in encouraging sustainable finance (Ahlström 2019). Taking advantage of these
13 hotspots may be crucial in overcoming path dependencies and setting new ones in motion.

14
15 One possible positive turn in this regard is the acceleration in investing in the environment (impact and
16 ESG) globally: for instance, there is evidence that some institutional investors are divesting from coal,
17 potentially auguring well for the future (Richardson 2017). The encouragement of governance and
18 policy reforms that could facilitate similar expansions of investment in sustainable firms and sectors
19 (Clark et al. 2018; Owen et al. 2018) could contribute to the dynamic feedback that gives a transition
20 lift and injects momentum into it. Also, the degrowth movement, with its focus on sustainability over
21 profitability, has the potential to speed up transformations using alternative practices like fostering the
22 exchange of non-monetary goods and services if large numbers of stakeholders want to invest in these
23 areas (Chiengkul 2017).

24 25 **17.4.4 Institutional capacities and multi-level governance**

26 Capable institutions and multi-level governance often support the inter-agency coordination and
27 stakeholder coalitions that drive sustainable transitions. Such institutions and governance arrangements
28 are frequently required to formulate and implement the multi-sectoral policies that spur the adoption
29 and scaling of innovative solutions to climate change and other sustainable development challenges.
30 For example, such institutional and governance conditions have helped support the industrial policies
31 that will be needed to spread renewables through the creation of domestic supply chains (Zenghelis
32 2020) or to pilot CDR methods (Quarton and Samsatli 2020).

33 However, government agencies with climate and other remits do not always work well together: the
34 absence of coordination and consensus building mechanisms can further deepen inter-agency conflicts
35 that stall a transition. These challenges appear not only within but also between levels of decision-
36 making. Studies of developing megacities, for instance, have found the lack of mechanisms promoting
37 vertical cross-level integration to be a sizable constraint on decarbonisation (Canitez 2019). Differences
38 in perspectives across non-state actors can similarly frustrate transitions in areas such as green buildings
39 (Song et al. 2020).

40
41 Here coordination complicates matters: coalition-building may require mutually reinforcing changes to
42 institutions and policies. For example, decentralized renewable energy has made progress in Argentina,
43 but consumer electricity subsidies give agencies and firms supporting conventional energy an advantage
44 over those promoting renewable energy. Similarly, the lack of concrete guidance in green finance
45 policies can deprive government agencies and other stakeholders of the information needed to balance
46 ecological and financial goals (Wang and Zhi 2016). Many of these challenges can be particularly
47 formidable in developing countries, where agencies lack sufficient financial and other capacities. A lack
48 of government funds to cover ongoing maintenance costs along with resource shortages in rural
49 locations can pose constraints on sustainable energy (Schaube et al. 2018).

50
51 Building inter-agency or multiple stakeholders is frequently challenging because of the mutually
52 reinforcing interactions between institutions and ideas. The imperceptible embedding of long-standing
53 development paradigms (such as 'grow now, clean up later') in agency rules and standard operating
54 procedures can make changes to governance arrangements challenging. This is partly because these

1 rules and procedures can also shape the interests of key decision-makers (e.g., the head of an
2 environmental agency). For some, this suggests a need to look not just at changing prevailing ideas and
3 interests, but also at broader institutional and governance arrangements (Kern 2011).
4

5 However, institutional and governance reforms can be more than a technical exercise. Political,
6 economic and other power relations can lock in dominant institutional and economic structures, making
7 the integration of climate and sustainable development agendas exceedingly difficult. For example,
8 though there have been recent reforms, the initial lack of early progress in Australia's energy transition
9 is partly attributable to institutions of political economy being oriented to providing steady supplies of
10 affordable fossil fuels (Warren et al. 2016).
11

12 This suggests that it is important to look closely at the pre-existing political economic system as well
13 as the institutional context and capacities in assessing the prospects for transitions to sustainability.
14 Furthermore, this is how existing institutions interact with ideas that often strengthen lock-ins. To
15 illustrate, studies have shown that the status-quo orientations of leaders (including decision-makers'
16 disciplinary backgrounds, world views and perceptions of risk) (Willis 2018), as well as the
17 organizational culture and management paradigms within which they operate, affect the speed and
18 ambitions of climate policies (Rickards et al., 2014).
19

20 Some studies have focused on factors that can break institutional and ideational lock-ins (Arranz 2017),
21 while others have found that intentional higher-level (or, in the language of socio-technical transitions,
22 "landscape") pressures can be the destabilizing force needed to move transitions forward (Falcone and
23 Sica 2015). Often the state or national government (as the sovereign that determines how resources are
24 used and allocated) can play a key role in destabilizing incumbent energy regimes, a role that is
25 significantly strengthened by public support (Arranz 2017; Avelino et al. 2016). However, this role is
26 not limited to government insiders. In some contexts, regime outsiders have also played a pivotal
27 role in destabilizing regimes by combining persuasive narratives that gain market influence (Arranz
28 2017). Carbon-intensive luxury goods and services for wealthy consumers, for instance, especially if
29 applied at the "acceleration" phase of a transition, can help transform long-term social practices and
30 behaviour and dissolve the "structural imperative for growth" (Wiedmann et al. 2020). In a similar
31 fashion, environmental taxes can remove "locked-in" technology and place pressure on dominant
32 regimes to become more sustainable (Bachus and Vanswijgenhoven 2018).
33

34 In many contexts, it is not multiple institutional and policy variables that come together to break
35 unsustainable inertias. In South Korea, where the state was an initiator and enabler of change, the clean-
36 energy transition took much longer than anticipated due to private-sector resistance. However, when
37 policy-makers focused on incorporating adaptive learning and flexibility into their decision-making,
38 public- and private-sector interests gradually converged and joined with top-down policy-making to
39 drive the transition forward (Lee et al. 2019). Thus, a political strategy can help align the interests and
40 institutions needed to break lock-ins.
41

42 This becomes clear in studies that show that political coalitions can affect the speed of transitions (Hess
43 2014). These same studies show that incumbent industry coalitions are now competing with 'green'
44 coalitions in terms of campaign spending over environmentally-friendly ballot proposals (Hess 2014).
45 Another way of shifting political-economic incentives is by offering a realistic exit strategy for
46 incumbents, like interventions that provide long-term incentives for renewable energy firms (de
47 Gooyert et al. 2016; Hamman 2019).
48

49 Overall, the previous subsection suggests that complementary policies and institutions that
50 simultaneously integrate across multiple sectors and scales and also alter political economic structures
51 that lock in carbon-intensive energy system are more likely to move a sustainable transition forward
52 (Burch 2010). Yet, despite a trend in climate governance towards greater integration and inclusivity and
53 certain other novel governance approaches, traditional approaches to governance and a tendency to
54 incrementalism remain dominant (Holscher et al. 2019). Building the governance arrangements and

1 capacities that prioritize climate change across all sectors and scales while destabilizing entrenched
2 interests and putting pressure on existing norms, rules and practices is still needed in many contexts
3 (Holscher et al. 2019).

4
5 At least three themes require further research in the scholarship on governance of transitions: 1) the role
6 of coalitions in supporting and hindering acceleration; 2) the role of feedback, through which policies
7 may shape actor preferences, which in turn create stronger policies; and 3) the role of broader contexts
8 (political economies, institutions, cultural norms, and technical systems) in creating conditions for
9 acceleration (Roberts et al. 2018). Importantly, these themes may serve as both barriers to and
10 opportunities for transitions (ibid.).

11 **17.4.5 Equity in a just transition**

12
13 Energy justice, although increasingly being emphasized (Pellegrini-Masini et al. 2020), has been under-
14 represented in the literature on sustainability and in debates on energy transitions, and it remains a
15 contested term with multiple meanings (Green and Gambhir 2020). Energy justice includes
16 affordability, sustainability, equality (accessibility for current and future households) and respect
17 (ensuring that innovations do not impose further burdens on particular groups) (Fuso Nerini et al. 2019).
18 Furthermore, it suggests that a just transition is a shared responsibility among countries that are making
19 more rapid progress towards net negative emissions and those economies that are focused on pressing
20 development priorities related to improved health, well-being and prosperity (van den Berg et al. 2020).

21
22 Looking at climate change from a justice perspective means placing the emphasis on a) the protection
23 of vulnerable populations from the impacts of climate change; b) mitigating the effects of the
24 transformations themselves, including easing the transition for those whose livelihoods currently rely
25 on fossil fuel-based sectors; and c) envisaging an equitable decarbonized world. Neglecting issues of
26 justice risks a backlash against climate action generally, particularly from those who stand to lose from
27 such actions (Patterson et al. 2018), and it will also have implications for the pace, scale and quality of
28 the transition. Explicit interventions to promote sustainability transitions that integrate local spaces into
29 the whole development process are necessary but not sufficient in creating a just transition (Breukers et
30 al. 2017; Ehnert et al. 2018b).

31
32 Renewable energy transitions in rural, impoverished locations can simultaneously reinforce and disrupt
33 local power structures and inequalities. Policy interventions to help the most impoverished individuals
34 in a community gain access to the new energy infrastructure are critical in ensuring that existing
35 inequalities are not reinforced. Individuals who are empowered by energy development projects can
36 influence the onward extension of sustainable energy to other communities (Ahlborg 2017). In Denmark
37 in the 1970s, for example, grassroots windmill cooperatives opened a pathway to the creation of one of
38 the world's largest wind-energy markets. The unique dynamics of grassroots-led changes mean that
39 new technologies and low-carbon initiatives develop strong foundations by being designed, tested and
40 improved in the early stages with reference to the socio-political contexts in which they will grow later
41 (Ornetzeder and Rohrer 2013).

42
43 Intersectional theory can shine a light on the hidden costs of resource extraction, as well as renewable
44 energy development (see, for instance, (Chatalova and Balmann 2017), which go beyond environmental
45 or health risks to include the socio-cultural impacts on both communities adjacent to these sites and
46 those who work in them (Daum 2018). Indeed, development decisions often do not properly integrate
47 the burdens and risks placed on marginalized groups, like indigenous peoples, while risk assessments
48 tend to reinforce existing power imbalances by failing to differentiate between how benefits and risks
49 might impact on certain groups (Healy et al. 2019; Kojola 2019). In some cases, such as the deployment
50 of small-scale solar power in Tanzania by a non-profit organization, an explicit gender lens on the
51 impacts of energy poverty revealed the significant socio-economic benefits of improving access to
52 renewable energy (Gray et al. 2019).

1 **17.4.6 Holistic planning and the nexus approach**

2 Poor sectoral coordination and institutional fragmentation have triggered a wide range of unsustainable
3 uses of resources and threatened the long-term sustainability of food, water and energy security (Rasul
4 2016). Greater policy coherence among the three sectors is critical to moving to a sustainable and
5 efficient use of resources (United Nations 2019), given that political ambition, values, the energy mix,
6 infrastructure and innovation capacities collectively shape transition outcomes (Neofytou et al. 2020).
7 Capacity- and coalition-building, particularly among sub-national and non-state actors (e.g. non-
8 governmental organizations) is a particularly important enabler of greater coherence (Bernstein and
9 Hoffmann 2018). The nexus approach, a systems-based methodology that focuses attention on the many
10 ways in which natural resources are deeply interwoven and mutually interdependent, can strengthen
11 coordination and help to avoid maladaptive pathways (Cremades et al. 2016).

12
13 A major shift is required in the decision-making process in the direction of taking a holistic view,
14 developing institutional mechanisms to coordinate the actions of diverse actors and strengthening
15 complementarities and synergies (Nikas et al. 2020; Rasul 2016). Currently, nexus approaches have
16 moved from purely conceptual arguments to application and implementation. (Liu et al. 2018) suggest
17 the need for a systematic procedure and provide perspectives on future directions. These include
18 expanding nexus frameworks that take into account interaction linkages with the SDGs, incorporating
19 overlooked drivers and regions, diversifying nexus toolboxes and making these strategies central to
20 policy-making and governance in integrating and implementing the SDGs.

21
22 In respect of processes, (Seyfang and Haxeltine 2012) found a lack of realistic and achievable
23 expectations among both members (internally) and the wider public (externally), which hampers the
24 acceleration of transitions. This movement could concentrate strategically on developing and promoting
25 short-term steps towards shared long-term visions, including clearly identifiable goals and end-points.
26 Sustainability science must link research on problem structures with a solutions-oriented approach that
27 seeks to understand, conceptualize and foster experiments in how socio-technical innovations for
28 sustainability develop, are diffused and are scaled up (Miller et al. 2014).

29
30 Various strategies and processes have been explored that might facilitate the translation of barriers into
31 enablers, thus accelerating transitions to sustainable development. Common themes include frequent
32 monitoring and system evaluation to reveal the barriers in the first place, the collaborative co-creation
33 and envisioning of pathways toward sustainable development, ambitious goal-setting, the strategic
34 tackling of sources of path dependence or inertia, iterative evaluations of progress and risk management,
35 adaptive management and building in opportunities for agile course-correction at multiple levels of
36 governance (Burch et al. 2014; Halbe et al. 2015). Given the political infeasibility of stable, long-term
37 climate policies, the better choice may be to embrace uncertainty in specific policies but entrench the
38 low-carbon transition as the overarching goal. Framing climate policy too narrowly, rather than taking
39 a more holistic, sustainable development-oriented approach, may tie success to single policies, rather
40 than allowing for system-wide change.

41
42 Decarbonisation may be encouraged by embedding the transition in a broader socio-economic agenda,
43 focusing on constructing social legitimacy to justify the transformation, encouraging municipalities
44 with a material interest in the transition and reforming institutions to support the long-term transition
45 goals (Rosenbloom et al. 2019). In jurisdictions where climate and energy policy have been integrated
46 and harmonized, such as the UK, progress has been made in transitioning to sustainable energy (Warren
47 et al. 2016).

48
49 Developing countries that are rich in fossil fuels now have an opportunity to reset their development
50 trajectories by focusing on those opportunities that will offer resilient development in land-use change,
51 low-carbon energy generation and not least more efficient resource-planning (UN- UNDRR 2019).
52 Resource-rich developing countries can choose an alternative pathway by deciding to monetize carbon
53 capital and diversifying away from the high-carbon aspects of risk. Countries rich in hydrocarbons can

1 diversify their energy mix and maximize their renewable energy potential. For instance, Namibia, a net
2 importer of electricity, is seeking to reduce its current dependence on hydrocarbons by promoting solar
3 energy. The government has issued permits allowing independent power producers (IPPs) to sell
4 directly to consumers, thus ending the monopoly hitherto enjoyed by the state utility company
5 NamPower (Kruger et al. 2019).

6
7 Cities are important spaces where the momentum to achieve low-carbon transitions can be built (Burch
8 2010; Holscher et al. 2019; Shaw et al. 2014), especially where centralized energy structures and
9 national governance and politics are posing deep-rooted challenges to change (Dowling et al. 2018;
10 Meadowcroft 2011). Cities can enter networks and partnerships with other cities and multilevel actors,
11 spaces that are important for capacity-building and accelerating change (Dale et al. 2020; Heikkinen et
12 al. 2019; Westman et al. 2021).

13
14 Addressing the uncertainties and complexities associated with locally, regionally and nationally
15 sustainable development pathways requires creative methods and participatory processes. These may
16 include powerful visualizations that make the implications of climate change (and decarbonization)
17 clear locally (Shaw et al. 2014; Sheppard et al. 2011), other visual aids or “progress wheels” that
18 effectively communicate the relevant contexts (Glaas et al. 2019), storytelling and mapping, and both
19 analogue and digital games (Mangnus et al. 2019).

22 17.5 Conclusions

23 This chapter has been concerned to assess the opportunities and challenges for acceleration *in the*
24 *context of sustainable development*. As such, many of the claims reviewed involve not only increasing
25 the speed of the transition but also ensuring that it is just, equitable and delivers a wider range of
26 environmental and social benefits. A sustainability transition requires removing the underlying drivers
27 of vulnerability and high emissions (quality and depth) while aligning the interests of different
28 communities, regions, sectors, stakeholders and cultures (scale and breadth).

29
30 Interest in a sustainability transition has grown steadily over the history of the IPCC and of climate and
31 related policy processes. That interest hit a high point in 2015 with the Paris Agreement and the 2030
32 Agenda for Sustainable Development and its 17 SDGs. It has continued to remain high as countries
33 have issued NDCs on climate change, VNRs on the SDGs and, in some instances, integrated climate
34 and SDG plans (or similarly themed integrated actions, e.g. circular economy plans). Interest has also
35 gained momentum as local governments, businesses and other stakeholders have followed suit with
36 climate change- or SDG-related plans.

37
38 Implementing many of the recent pledges, however, has proved challenging. Part of the challenge is a
39 need to address everything from public policies and prevailing technologies to individual lifestyles and
40 social norms to governance arrangements and institutions with associated political economy
41 implications. These factors can lock in development pathways and prevent transitions from gathering
42 the momentum needed for large-scale transformations of socioeconomic systems. Another
43 consideration is that transition pathways are likely to vary across and within countries due to different
44 development levels, starting points, differential vulnerabilities, capacities, agencies, geographies, power
45 dynamics, political economies, ecosystems and other contextual factors.

46
47 Even with this diversity, prominent lines of economic, institutional, psychological and systems thinking
48 have reflected on interventions that can enable transitions. Because these disciplines often focus on
49 different levels of analysis and draw upon diverse analytical methods and empirical evidence, the
50 recommended interventions also tend to vary. For instance, economic arguments often point to the need
51 for targeted regulation or investments, institutional claims centre on multilevel governance reforms, and
52 psychology encourages participation to change mind sets and social norms. Systems-level perspectives
53 offer a useful frame for bringing together these views, but may not capture the richness and details of

1 them treated separately. Greater inter- and transdisciplinary research is needed to integrate the more
2 focused interventions and show how they work together in a system. Such research will be particularly
3 important for working on the concern running through these studies: strengthening synergies between
4 climate and the broader sustainable development agenda.
5

6 National and sub-national, sectoral and cross-sectoral, short- and long-term transition studies have
7 assessed the links between sustainable development and mitigation policies and synergies and the trade-
8 offs between the different policy domains. Some general conclusions can be drawn on synergies and
9 trade-offs, despite the actual impacts of policy implementation depending on scale, context and the
10 development starting point.

11
12 From a cross-sectoral perspective, it can be concluded that the AFOLU sector offers many low-cost
13 mitigation options with synergetic SDG impacts, which, however, can also create trade-offs between
14 land-use for food, energy, forest and biodiversity. Some options can help to mitigate such trade-offs,
15 like agricultural practices, forest conservation and soil carbon sequestration. Lifestyle changes,
16 including dietary changes and reduced food waste, could jointly support the SDGs and mitigation.
17 Industry also offers several mitigation options with SDG synergies, for example, related to energy
18 efficiency and the circular economy. Some of the renewable-energy options in industry could indicate
19 some trade-offs in relation to land use, with implications for food- and water security and costs. Cities
20 provide a promising basis for implementing mitigation with SDG synergies, particularly if urban
21 planning, transportation, infrastructure and settlements are coordinated jointly. Similarly, studies of the
22 building sector have identified many synergies between the SDGs and mitigation, but there are issues
23 related to the costs of new technologies. Also, in relation to households and buildings, important equity
24 issues emerge due to the ability of low-income groups to afford the introduction of new technologies.
25 Altogether these cross-sectoral conclusions create a need for policies to address both synergies and
26 trade-offs, as well as for coordination between different sectoral domains. Context-specific assessments
27 of synergies and trade-offs are here important, as is sharing the benefits and costs associated with
28 mitigation policies.
29

30 Several opportunities for creating SDG synergies and avoiding trade-offs have also been identified in
31 relation to integrated adaptation and mitigation policies. The AFOLU sector has a large potential for
32 integrating adaptation and mitigation policies related to agriculture, bioenergy crops, forestry and water
33 use. As was concluded for mitigation options, integrated adaptation and mitigation policies also entail
34 the risks of creating trade-offs in relation to food, water, energy access and biodiversity. There are
35 several potentially strong links between climate-change adaptation in industry and climate-change
36 adaptation more generally. Various supply chains can be affected by climate change, and mitigation
37 options related to energy and water supply can be disrupted by climate events, implying that great
38 benefits may come from integrating adaptation in industrial planning efforts. Adaptation options in
39 industry can imply increasing the demand for packaging materials such as plastics and for access to
40 refrigeration, which are also major sources of GHG emissions, which then would require further
41 mitigation options. Mitigation and the co-benefits of adaptation in urban areas in relation to air quality,
42 health, green jobs and equality issues can in most cases to be synergetic and can also support the SDGs.
43 One exception are compact cities, with their trade-offs between mitigation and adaptation because
44 decreasing urban sprawl can increase the risks of flooding and heat stress. Detailed mapping of
45 mitigation and adaptation in urban areas shows that there are many, very close interactions between the
46 two policy domains and that coordinated governance across sectors is therefore called for.
47

48 Meeting the ambitions of the Paris Agreement will require phasing out fossil fuels from energy systems,
49 which is technically possible and is estimated to be relatively low in cost. However, studies also show
50 that replacing fossil fuels with renewables can have major synergies and trade-offs with a broader
51 agenda of sustainable development if a balance is established in relation to land use, food security and
52 job creation (McCollum et al. 2018). Furthermore, the transition to low-emission pathways will require
53 policy efforts that also address the emissions locked into existing infrastructure, like power plants,
54 factories, cargo ships and other infrastructure already in use: for example, today coal-fired power plants
55 account for 30% of all energy-related emissions. Thus, even though the transition away from fossil fuels

1 is desirable and technically feasible, it is still largely constrained by existing fossil fuel-based
2 infrastructure and the existence of stranded investments. The “committed” emissions from existing
3 fossil-fuel infrastructure may consume all the remaining carbon budget in the 1.5°C scenario or two
4 thirds of the carbon budget in the 2°C scenario.

5
6 Stranded hydrocarbon assets, including hydrocarbon resources and the infrastructure from which they
7 are produced, and investments made in exploration and production activities, are likely to become
8 unusable, lose value, or may end up as liabilities before the end of the anticipated economic lifetime.
9 This phenomenon is rapidly becoming a global reality as social norms change and the pressure to reduce
10 emissions mounts. Energy and other forms of structural inequities are likely to make the transition
11 planning more challenging, especially given stranded assets.

12
13 Countries dependent on fossil fuel income will need to forego these revenues to keep well within the
14 Paris agreement requirements and align with the rapidly growing divestment movement. Climate
15 injustice, energy poverty, and COVID 19 have reduced the space and maneuverability for developing
16 countries to innovate and use surplus funds to procure new and clean technologies. A rising debt burden
17 already hamstrings many. Decisions on how to spend the remaining carbon budget and who has the
18 right to decide on what to do with existing fossil fuels reflect the complexity of the transition and its
19 non-linearity character. Given the asymmetrical dimension of energy production, distribution, and use,
20 it is likely that stranded assets will have implications for oil-producing countries, especially for early
21 producers who perceive that newfound oil and gas will open doors to new forms of prosperity.

22
23 While the transitional drivers are not in place in some developing countries, i.e., technology,
24 infrastructure, knowledge, and finance, among others, investing in new forms of renewable energy for
25 land, energy, or water sectors will see the emergence of a more diversified economy and one less
26 vulnerable to carbon and other exogenous risks. The transition away from fossil fuels will come with
27 hard choices. Still, these choices can enable a sustainable development world and reduce the many
28 asymmetries and injustices inherent in the current system, not least the gaping energy disparities that
29 divide the developed and the developing world.

30
31 Equality and justice are central dimensions of transitions in the context of sustainable development.
32 Viewing climate change through the lens of justice requires a focus on the protection of vulnerable
33 populations from the impacts of climate change, addressing the unequal distribution of the costs and
34 consequences of the transitions themselves, including for those whose livelihoods are rooted in fossil
35 fuel-based sectors, and developing more creative and participatory processes for envisioning an
36 equitable decarbonized world. Neglecting issues of justice will have implications for the pace, scale and
37 quality of the transition.

38
39 Ultimately, the evidence demonstrates that there is rarely any one single factor promoting or preventing
40 transitions. A constellation of elements come into play, including technological innovations, shifts in
41 markets, social and behavioural dynamics, and governance arrangements. Indeed, transitions require an
42 examination of the role of values, attitudes, beliefs and the structures that shape behaviour, as well as
43 the dynamics of social movements and education at multiple levels. Likewise, technological and social
44 innovation both play an important role in enabling transitions, highlighting the importance of multi-
45 institutional and multi-stakeholder actors building institutional support networks, facilitating
46 collaboration between sectors and actors, and promoting learning and social change. Financial tools and
47 economic instruments are crucial enablers, since many forms of transformational change to energy
48 systems are not possible when financial systems still privilege investing in unsustainable, carbon-
49 intensive sectors. These instruments are deployed within the context of the multi-level governance of
50 climate change, which suggests the importance of complementary policies and institutions that
51 simultaneously integrate across multiple sectors and scales to address the multiple sources of lock-in
52 that are shaping the current carbon-intensive energy system. Systems-oriented approaches, which
53 holistically address the intersections among climate, water and energy (for instance), have significant
54 potential to reveal and help avoid trade-offs, foster experimentation, and deliver a range of co-benefits
55 on the path towards sustainable development.

Frequently Asked Questions (FAQs)

FAQ 17.1 Will decarbonisation efforts slow or accelerate sustainable development transitions?

Sustainable development offers a comprehensive pathway to achieving ambitious climate change mitigation goals. Sustainable development requires the pursuit of synergies and the avoidance of trade-offs between the economic, social and environmental dimensions of development. It can thus provide pathways that accelerate progress towards ambitious climate change mitigation goals. Factoring in equality and distributional effects will be particularly important in the pursuit of sustainable policies and partnerships, and in accelerating the transition to sustainable development. Using climate change as a key conduit can only work if synergies across sectors are exploited and if policy implementation is supported by national and international partnerships.

The speed, quality, depth and scale of the transition will depend on the developmental starting point, that is, on explicit goals as well as the enabling environment consisting of individual behaviour, mindsets, beliefs and actions, social cohesion, governance, policies, institutions, social and technological innovations etc. The integration of both climate change mitigation and adaptation policies in sustainable development is also essential in the establishment of fair and robust transformation pathways.

FAQ 17.2 What role do considerations of justice and inclusivity play in the transition towards sustainable development?

Negative economic and social impacts in some regions could emerge as a consequence of ambitious climate change mitigation policies if these are not aligned with key sustainable development aspirations such as those represented by the SDGs on 'no poverty, energy-, water- and food access' etc., which could in turn slow down the transition process. Nonetheless, many climate change mitigation policies could generate incomes, new jobs and other benefits. Capturing these benefits could require specific policies and investments to be targeted directly towards including all parts of society in the new activities and industries created by the climate change mitigation policies, and that activities that are reduced in the context of transitions to a low carbon future, including industries and geographical areas, are seeing new opportunities. Poor understanding of how governance at multiple levels can meet these challenges to the transition may fail to make significant progress in relation to national policies and a global climate agreement. It may therefore either support or weaken the climate architecture, thus constituting a limiting factor.

FAQ 17.3 How critical are the roles of institutions in accelerating the transition and what can governance enable?

Institutions are critical in accelerating the transition towards sustainable development: they can help to shape climate change response strategies in terms of both adaptation and mitigation. Local institutions are the custodians of critical adaptation services, ranging from the mobilisation of resources, skills development and capacity-building to the dissemination of critical strategies. Transitions towards sustainable development are mediated by actors within particular institutions, the governance mechanisms they use as implementing tools and the political coalitions they form to enable action. Patterns of production and consumption have implications for a low-carbon development, and many of these patterns can act as barriers or opportunities towards sustainable development. Trade policies, international economic issues and international financial flows can positively support the speed and scale of the transition; alternatively, they can have negative impacts on policies that may inhibit the process. Nonetheless, contextual factors are a fundamental part of the change process, and institutions and their governance systems provide pathways that can influence contextual realities on the ground. For instance, politically vested interests may lead powerful lobby groups or coalition networks to influence the direction of the transition, or they could put pressure on a given political elite through the

1 imposition of regulatory standards, taxation, incentives and policies that may speed or delay the
2 transition process. Civil society institutions, such as NGOs or research centres, can act as effective
3 governance ‘watch dogs’ in the transition process, particularly when they exercise a challenge function
4 and question government actions in respect of transitions related to sustainable development.
