Pressure Drops VALUE KV

Directions for the Metric Pressure Drop Chart based on 160°F supply Temperature

STEP 1: Find the flow Rate in GPM

The flow rate is the output of the radiator at 160°F divided by 10,000 = GPM

STEP 2: Convert From GPM to L/H Multiply GPM x 227 = Flow Rate in L/H

STEP 3: Find Pressure Drop In kPA Look up the chart from L/Hr to find the pressure drop in KPA

STEP 4: Convert kPA to Feet of Head Multiply kPa x 0.3346 = Pressure drop in Feet of Head 1bar=33.46 ft/head

Example: K2 24 x 24

Output at 160°F is 3546 Flow Rate in GPM = 3546/10000 = .3546GPM GPM x 227 = litre/hour .3546 x 227 = 80.49 L/H 80.49 = 0.0008 bar 0.0008 x 33.46 = 0.026768 ft/h

Calculating Radiator Output

32 Calculating Existing Cast Iron Radiator Output in BTU's/Hr

To find the output of a cast iron radiator, you need to know the surface area in square feet of the radiator. Follow these steps to calculate the square feet of radiation. NOTE: Column and Tube cast iron radiators are the two main types.

Step #1. Calculate the square footage of one section of the radiator.

- Measure height of section
- Measure width of section
- Find square feet of section in Chart # 1 for COLUMN or Chart # 2 for TUBE type radiator

Step #2. Multiply the square feet of the one section by the number of sections. Equals the cast iron radiator's total square foot of radiation.

Step #3. Multiply the total square foot of the radiator by the BTU output per square foot according to the heating supply temperature, Chart #3.

Please note that a house heated with all cast iron radiators, the supply temperature generally does not exceed 140°F or 90 BTU's per square foot output for the cast iron radiator.
